Canadian laboratory. One of the most important of his recommendations was that the company should sell its supplies to physicians. He thought a business of five millions could be done by the adoption of this policy. He also suggested the manufacture of dental supplies by the company, and the acquirement by purchase of established patent medicines, instancing a certain proprietary children's cathartic, and analysing the value of such a purchase. He announced a favorable vote by the stockholders on the proposition to increase the capital of the company and recommended that it should be a \$10,000,000 issue. He suggested the adoption of the premium certificate plan by the company, similar to the coupon plan of the United Cigar Co. The general session on Thursday authorized the increase of capital stock and the issue of premium coupons. At this meeting Mr. Goddard announced that it was probable that the A. D. S. members would attend the San Francisco exhibition in one of the company's own steamships. The following gentlemen were elected as directors for three years: C. H. Goddard, G. W. Luft, W. C. Anderson, Otto G. Hottinger, Sidney C. Yeomans. Dr. Anderson presented resolutions against the illegal sale and distribution of cocaine and heroin, which were adopted. The entertainment features were many and elaborate. They comprised theatre parties, banquets, and a grand ball on Friday evening. At a meeting of the new board of directors the following officers were chosen for the coming year: President, Dr. William C. Anderson, Brooklyn, N. Y.; Vice-Presidents, E. L. Weston, Syracuse, N. Y.; G. W. Stevens, Detroit, Mich.; G. N. Cherrington and E. W. Stucky; Secretary and Manager, C. H. Goddard; Treasurer, G. W. Luft.

RESOLUTIONS ADOPTED BY THE NATIONAL DRUG TRADE CONFERENCE RESPECTING PROPOSED DRUG LEGISLA- TION.

The National Drug Trade Conference is composed of delegates from the national organizations of those engaged and interested in the manufacture, wholesaling and retailing of the hundreds of pharmaceuticals prescribed or ordered by physicians, dentists and veterinarians.

The constituent members are:

The American Pharmaceutical Association, a scientific rather than a commercial body, organized in 1851.

The National Association of Retail Druggists, now some fifteen years old, representing the commercial side of retail pharmacy.

The National Wholesale Druggists' Association, organized thirty-eight years ago for the mutual benefit of the wholesale drug trade.

The American Association of Pharmaceutical Chemists, composed of some fifty or more manufacturers, most of whom deal directly with the medical profession; and

The National Association of Manufacturers of Medicinal Products, embracing practically all of the larger pharmaceutical manufacturing houses having close relations with the drug trade.

Few people, even in professional and legislative circles, realize how many millions are invested in the manufacture of drugs in various forms that are not offered to the public and are not intended to reach the consumer except as dispensed upon the prescription of or administered by the doctor, the dentist or the veterinarian.

Legislation in the past has been entirely without regard to the lawful business of those thus represented in the National Drug Trade Conference; and much legislation now proposed ignores the effect it would have upon interests not more important to the manufacturers and dealers themselves than to the public.

For example: In the legislature of one of the states there was recently introduced an inspection bill intended to prevent the sale of "patent medicines" until they had been analyzed and found to contain medicinal ingredients that warranted whatever therapeutic claims had been made for them. As worded it required the manufacturer of any medicinal compound not recognized in the United States Pharmacopœia or National Formulary to pay an annual inspection fee of \$25.00 for each such compound offered for sale in that state.

This meant nothing to the "patent medicine" proprietor, whose tax would have been \$25.00 multiplied by the few (in most cases but one) products he offered to the public.

The varying views of the medical profession require purveyors to furnish thousands of combinations in fluid, solid, pill or tablet form that are not mentioned in the United

States Pharmacopœia or National Formulary. Such a law would have imposed an annual tax upon the pharmaceutical manufacturer of thousands of dollars. They could not have complied and would have been compelled to supply doctors, dentists and veterinarians in interstate commerce, which would have resulted in untold loss to the drug trade of that state.

The work of the National Drug Trade Conference has been and will continue to be constructive. This is assured by its connection with the Harrison bill, intended to prevent the practical nullification of the anti-narcotic laws of the several states by the natural operations of interstate commerce. The work was commended by Congressmen Harrison and Mann in the discussion resulting in the passage of the bill by the House June 26, 1913; and it may well be said that never was a more orderly attempt made to effect reasonable legislation efficient for the purpose of minimizing a crying evil without injuring lawful interests. The organization and work of the Conference in this connection may well be studied as something unique and highly commendable in constructive legislation.

It is therefore urged that the views respecting pending measures in Congress and some state legislatures expressed in the accompanying resolutions deserve careful consideration, and no hasty legislation amending or additive to existing drug law be enacted during the considerable period necessary for studying and harmonizing the various statutes which now lack desired uniformity; especially in features more immediately concerning interstate commerce.

Federal Food and Drugs Act Should not be Amended Prior to Publication of New Revisions of United States Pharmacopœia and National Formulary.

WHEREAS, The Conference has been organized to secure uniformity in State and Federal laws relating to the adulteration and misbranding of drugs; and,

WHEREAS, Such uniformity is now being sought by the Commission on Uniform Laws and also by the American Bar Association; and,

WHEREAS, The American Bar Association has recommended that such uniformity be secured by the various States conforming their laws to the Federal act; and,

WHEREAS, Further hasty State and Federal legislation respecting the adulteration and misbranding of drugs will add to the confusion now existing; therefore, be it

Resolved, That this National Drug Trade Conference earnestly recommend that no new

laws relating to the adulteration and misbranding of drugs be enacted by any State during the present session of its legislature, unless its purpose be to bring the law in conformity with the Federal law; and be it further

Resolved, That this Conference recommend that the Federal law should not be amended prior to the publication of the new revision of the United States Pharmacopœia and National Formulary, lest greater lack of uniformity be effected.

On Bi-Chloride of Mercury and Other Poison Legislation.

Resolved, That in recognition of the power of suggestion upon morbid and unbalanced minds, the National Drug Trade Conference does hereby urge upon the newspapers of the country that in reporting suicides and murders, details with respect to poisons, instruments, weapons or other methods used be, so far as possible, omitted.

WHEREAS, The United States Pharmacopœia and National Formulary, both standards of Federal and State food and drugs acts, are now in process of revision, and whereas, the Committee of Revision of the said volumes are considering for inclusion therein suitable regulations for forms, shapes, methods of packaging and labeling of tablets of bichloride of mercury and other dangerously toxic substances in order to plainly distinguish them from tablets which do not contain dangerously toxic substances; and,

WHEREAS, It is greatly desirable that all laws regulating the sale of poisonous tablets should be uniform and consistent with each other; therefore, be it

Resolved, That it is the opinion of the National Drug Trade Conference that Federal legislation upon the subject of tablets of mercury bichloride and other poisonous substances should be deferred until after the Revision Committee of the United States Pharmacopœia and National Formulary shall have made their reports in order to lessen the liability of conflict between Federal legislation and the provisions of the said United States Pharmacopœia and National Formulary.

Resolved, That it is the opinion of the National Drug Trade Conference that the adoption of suitable regulations for the shapes, colors, methods of packaging and labeling of tablets of bichloride of mercury for inclusion in the next revision of the United States Pharmacopœia or National Formulary is a matter of vital importance to the practice of pharmacy, the practice of medicine and the public health, and that we heartily recommend to the Committee of Revision of the United States Pharmacopœia and National Formulary that they take steps to include such regulations in such next revision of the Pharmacopœia; and be it further

Resolved, That this Conference tender to said Committee of Revision any assistance

it may be capable of rendering in the construction of such regulations; and be it further

Resolved, That any Federal legislation regulating the sale of mercury bichloride tablets should be confined to regulations respecting the form and style of packages in which such tablets are shipped in interstate commerce, and should not include the shipment of the chemical substance mercury bichloride as such.

Respecting Price Protection.

Resolved, That the Conference go on record as in favor of any constitutional and sound legislation that will enable the manufacturer or dealer of any article or brand of an article in which such manufacturer or dealer has an industrial right by patent, trade-mark, trade secret, copyright, design, or otherwise, to fix, maintain and protect the selling price thereof to the consumer, and thereby maintain the quality and reputation thereof, which is the inherent value to the public as well as to the manufacturer or dealer of an article called for and purchased under a trade name, or because of the features protected by any such industrial right; provided, such legislation does not open the way to the monopolization of the sale of any other article of the same kind or class which might otherwise be open to proper competition.

On Regulation Respecting Mailing of Poisons.

Resolved, That this Conference recommend to the postmaster general the adoption of the following regulation respecting the mailing of poisons in lieu of the one now ruling:

"Poisonous substances intended for internal or medicinal administration when packed in a metal container bearing the address of the sender, together with a label bearing the word 'Poison,' may be admitted to the mails under first-class postage rates."

Resolved, That the Committee on Revision of the United States Pharmacopœia be requested to consider the desirability of inserting in the forthcoming revision of the United States Pharmacopœia a section defining the word "Poison."

Action of the National Drug Trade Conference on the Elimination of the "Variation Provision" of the Food and Drugs Act of June 30, 1906.

NOTE.—The Food and Drugs Act of June 30, 1906, incorporates the following provision which, for convenience, is hereafter referred to as the "variation provision":

"Provided, That no drug defined in the United States Pharmacopœia or National Formulary shall be deemed to be adulterated under this provision if the standard of strength, quality or purity be plainly stated upon the bottle, box or other container thereof, although the standard may differ from that determined by the test laid down in the United States Pharmacopœia or National Formulary."

Dr. A. R. L. Dohme moved the adoption of the following resolution:

"Resolved, That it is the sense of this Conference that it is opposed to all legislation tending to eliminate the 'variation clause' from the food and drugs act."

Motion seconded.

Mr. Charles M. Woodruff stated that his association, the National Association of Manufacturers of Medicinal Products, was most vitally interested in this question and most earnestly opposed to any elimination of the "variation clause"; but that in all fairness such summary action as Dr. Dohme's resolution, if adopted, would effect should not be taken. He believed there were many who were honestly in favor of the absolute elimination of the "variation clause" to remedy some evils that had, perhaps, sprung up under it; but these advocates could be made to see the greater evils that would follow the elimination of the "variation clause"; and he further believed in constructive work, and that if the Conference got together with the representatives of such advocates some way of meeting the situation might be discovered, and a plan agreed upon that would save much legislative contention and long and expensive litigation to preserve industrial rights that would follow any law absolutely eliminating the "variation clause." He therefore moved the whole matter be referred to the Executive Committee for the purpose of effecting such conference.

Mr. James F. Finneran supported the argument of Mr. Woodruff in some interesting remarks, and seconded the motion, which was put to vote and unanimously carried.

Dr. M. I. Wilbert suggested that the Executive Committee of the Conference get in touch with the National Association of Food and Drug Commissioners.

BRIEF IN BEHALF OF THE HUGHES-BACON BILLS.

Submitted to the House Committee on Military Affairs:

1. This bill provides for a slight increase in the salaries of the Army Hospital Corps, and it is believed it will be of great benefit to this service.

2. The pharmacists of the United States are behind this bill. It was introduced in the House and in the Senate by the friends of the pharmacists. It is indorsed

and asked for by all the big organizations of pharmacists, such as the American Pharmaceutical Association, the National Association of Retail Druggists, the National Association of Drug Clerks, and by every State Pharmaceutical Association throughout the Union. The pharmacists of the United States are prominent in every community, and are working hard in behalf of this legislation, and not one of them have received or are receiving or are to receive a single cent for his efforts in this matter. The men of the Army Hospital Corps are themselves in such a position that they can not do anything. They hold no commissions, and rules are so arbitrary in the army that unless a man holds a commission, no matter how near to the hearts of the people is the improvement of his service, he is not authorized to do anything but hold his tongue.

The pharmacists are all located in centers of population, large or small as the case may be, and their places of business are always nuclei around which centers the active interests of each community. They are professional men. They see the Hospital Corps entered by ignorant, incompetent men at \$16 per month, and after many, many long years of service under commissioned medical officers who have never studied pharmacy, they are slowly advanced, the whole pharmaceutical service of the United States army being handled in this way; and there not being a man in it of a higher grade than sergeant first class.

3. In civil life, in every State in the Union, every man who practices pharmacy is required to work under a licensed pharmacist three or more years, or to be a graduate of a college of pharmacy, before he is even permitted to be examined for license, which he can only secure after having successfully passed a thorough examination before a board of five or more licensed pharmacists provided by the law of the State. The spirit of every State pharmacy law is being violated by present conditions in the United States Army Hospital Corps.

4. The total increase asked for is only \$168,876, or less than the cost of the cigar stumps thrown into the gutters each day by the American people, and this increase is asked that the lives and the health of our people who may serve in a military capacity away from homes and friends may be better protected.

5. The Army Hospital Corps, in time of

war, are in the midst of the battles and near the skirmish lines, binding up the spouting arteries and saving lives where the slightest delay means death, and bringing the wounded on stretchers to the field hospitals; they work shoulder to shoulder with the medical officers, who bear commissions and to whom all the glory goes for commendable work. In battle their casualties may run high; in 1905 the Surgeon General's report shows that in the percentages of killed and wounded their ratio was twice as great as that of the regular fighting line. Strenuous are their duties in time of battle. Such work comes occasionally, as war is desperate and irregular, but their work is also a steady, daily fight in time of peace, fighting not only ordinary diseases, but the most deadly contagious ones. They are ever on their firing line, fighting pestilence and disease not only during the day, but in the night time. The sick do not differentiate between daylight and darkness, unless it is that the vital forces seem lowest at the small hours before dawn, when more than usual watchfulness is needed.

6. The Army Hospital Corps, in addition to its work on the battle-field, its assistance in surgical work, its giving anesthetics, its taking care of the sick, its dispensing of dangerous drugs and poisons, its handling of delicate static, galvanic and X-ray electrical apparatus, it also has charge of the tremendously important work of the sanitary conditions of the camps, which, if not handled properly can, at any time, cause an outbreak of disease which will cost the country many valuable lives.

7. In our American wars we have always lost many, many more men by sickness and disease than by the missiles of the enemy. There was no exception to this dreadful condition of affairs in our recent Spanish-American war. The pharmacists of the United States were pleading with Congress for better pharmaceutical service in the army for several years before this war began, but conditions were not improved. The handling of medical supplies in that war was a disgrace to our American civilization. In the recent Russo-Japanese war, the Japanese lost far less men by sickness and disease than they did from missiles of the enemy. The pharmacists in their hospital corps bear commissions as second lieutenants, and were sent ahead and selected the camping places and analyzed all the drinking water supplies that proper sanitary conditions should be secured

as far as possible. Congress guards the right to commissions in the United States army so closely that there are no commissioned pharmacists in the Army Hospital Corps, and the salaries of the Hospital Corps are so meager that there is no inducement to pharmacists to enter the service, and pharmacists do not enter it. They do enter the United States Navy and Public Health Service, as these departments offer much better inducements.

8. The men who enter the Hospital Corps service have to start at \$16 per month. After the second enlistment they are paid \$19 per month. Then there is a \$1 increase after each enlistment, and after many years in the service they may finally reach their highest grade of Sergeant First Class, with a salary of \$50 per month and an increase of \$4 after the second enlistment. This bill also asks for an increase of \$3 per month for privates first class; for Sergeants, an increase of \$6 per month; for Sergeants first class, \$15 per month, and for the new grade of Sergeants Major, \$75 per month. No increase in number is asked for any of the grades. The only additional men asked for are thirty in the new grade of Sergeants Major.

9. The new grade of Sergeants Major will make the service more attractive than at present, and with a salary of \$75 for only thirty of the highest salaried men in the service, it does not begin to compare with the service in nearly all other civilized countries, as they give commissions to their pharmacists. In France, pharmacists rank as high as General of Brigade; in Germany they rank as high as Colonel, and even in Japan they are Second Lieutenants.

The National Guard in every State are under the same regulations as the United States army, but before the passage of the Dick bill such was not the case, and in every State steps were being taken to make the pharmacists of the National Guard Hospital Corps Second Lieutenants. This legislation was passed in one or two States and was all arranged and provided for to pass in a number of States at the next meetings of their legislatures, when the passage of the Dick bill made it necessary for the pharmacists of the United States to take up the matter with Congress.

11. Competent drug clerks all over the country draw salaries on the average of about \$100 per month; many get much more. Com-

petent drug clerks who are as good executive men as Sergeants first class are expected to be, and Sergeants Major would be required to be, readily obtain from \$150 to \$200 in civil life. There is not an institution teaching pharmacy in the United States which ever recommends the Army Hospital Corps to a single student as a pharmaceutical career.

12. The Army Hospital Corps, with such small salaries, is not as attractive to men as the other branches of the army service, and hence the corps has much difficulty in securing and retaining competent men. Dentists in the army, who take care of the teeth, get salaries of \$150. The duties of pharmacists are matters of life and death, and in civil life their financial compensation is fully as great as that of the dentists. The army band musicians of the lowest, or third class, begin at \$30 per month instead of \$16 as in the Hospital Corps; and as grades and service increase, goes up to \$99, against the highest grade in the Hospital Corps, which finally reaches \$74. Even the men who look after the sick mules are better paid than those who look after the sick soldiers.

13. In behalf of better pharmaceutical service in the army, we appeal to you. In behalf of our great American citizenship, we ask for such improvement in salaries that not only pharmaceutical wrecks may be attracted to the service, but that men of some pharmaceutical competency can afford to enter it.

In behalf of the lives of American citizens we appeal to you.

As a matter of economical administration of the Government of the United States we know that you can but fully realize that improvement in the Army Hospital Corps means a saving of health and of lives, and that such saving of health and life means more continued happiness among our people and the saving of heavy pensions.

This is a non-political matter. Democrats and Republicans have united in the past in putting the pharmaceutical service in the United States Navy and in the United States Public Health Service in better shape, and have given commissions to the naval pharmacists. What we ask for the profession of pharmacy in the United States Army is very modest indeed.

The present condition of pharmacy in the United States Army is a national disgrace.

Respectfully submitted,

GEORGE F. PAYNE.

Editorial Notes and Announcements

JAMES H. BEAL, Editor.....Scio, Ohio

ERNEST C. MARSHALL, Associate Editor,
63 Clinton Building, Columbus, Ohio

All communications for insertion in the JOURNAL, or respecting advertising should be sent to the Editor.

The Association does not accept responsibility for the opinions of contributors. Offensive personalities must be avoided.

Under the rules of the Postoffice the JOURNAL can be regularly mailed only to bona-fide paid subscribers. Subscriptions and association dues should be sent to the Treasurer, H. M. Whelpley, 2342 Albion Place, St. Louis, Mo.

Requests for back numbers, and claims for missing numbers should be sent to the Editor.

Claims for missing numbers will not be allowed if sufficient notice has not been given of change of address, and in no case if received later than sixty days from the date of issue.

REPRINTS.

If the request is made at the time copy is submitted, authors will be furnished with not to exceed 50 reprints, without cover, of papers accepted for publication in the JOURNAL.

Larger numbers of reprints will be supplied by the Stoneman Press Co. at the following prices, provided the order is received before the type has been distributed:

100 copies, 4 pages, no cover, \$2.50, with cover, \$4.50.

200 copies, 4 pages, no cover, \$3.00, with cover, \$5.50.

50 copies, 8 pages, no cover, \$2.75, with cover, \$4.50.

100 copies, 8 pages, no cover, \$3.50, with cover, \$5.00.

200 copies, 8 pages, no cover, \$4.50, with cover, \$6.50.

50 copies, 12 or 16 pages, no cover, \$4.00, with cover, \$5.50.

100 copies, 12 or 16 pages, no cover, \$5.00, with cover, \$6.50.

200 copies, 12 or 16 pages, no cover, \$6.50, with cover, \$8.00.

Orders for reprints may be sent either to the Editor, or to the Stoneman Press Co., Columbus, Ohio.

PROFESSOR RAUBENHEIMER RETIRES FROM EDITORIAL WORK.

Prof. Otto Raubenheimer has retired from the editorship of the Practical Druggist, and in future will devote himself to the practice of pharmacy and to his professorship in the College of Pharmacy of the University of New Jersey, and incidentally will continue to serve as a general bureau of information on matters pharmaceutical.

Like others of us, Prof. Raubenheimer has discovered that there is a limit to the quantity of work that can be disposed of in 24 hours.

CHAIRMAN OF THE SCIENTIFIC SECTION REQUESTS PAPERS.

Chairman E. A. Ruddiman, of the Scientific Section, desires it to be understood that he will welcome papers appropriate to his Section from any member of the Association.

In order to permit the proper arrangement of the program and the selection of papers for discussion, it is desirable that the papers be sent to the Chairman not later than thirty days prior to the meeting.

Dr. Ruddiman's address is 101 24th Ave., S., Nashville, Tenn.

WINNER OF THE BERGER PRIZE.

The Ernest Berger Prize consists of a nomination to membership in the A. Ph. A. and the first years' dues, and is awarded by Ernest Berger, of Tampa, Florida, to the candidate making the highest average in all branches before the Florida State Board of Pharmacy.

The latest winner of the prize is Mr. F. J. Collinson, of Gainesville, Fla. Mr. Collinson has our congratulations.

"PRESCRIPTIONS 3000 YEARS OLD."

The third of the special lectures at the College of Pharmacy of the University of the State of New Jersey in Jersey City was delivered February 27th by Dr. Felix Von Oefele of New York City, who is a recognized world-wide authority on medicine and pharmacy of Old Egypt, Babyolnia and As-

syria. Dr. Oefeled had received two stone tablets from Yale University containing cuneiform inscriptions which are probably some of the oldest prescriptions in the world. In his lecture, the speaker gave an outline of medicine and pharmacy in Egypt and especially in Babylonia, which was the seat of culture and science in that early period. Dr. Oefeled has made the study of cuneiform script as well as that of hieratics and hieroglyphs a specialty, and showed a number of records dating back to 1500 B. C.

ST. LOUIS COLLEGE MAKES CHANGES IN LIBRARY.

The St. Louis College of Pharmacy has placed its entire library in the Central Building of the St. Louis Public Library which is located very near the college building.

The college library has space to itself in the science reference room. The books and periodicals will remain the property of the college, but will be catalogued and cared for by the library as if the property of that institution.

Arrangements will be made for the students of the college to receive special drill in the use of pharmaceutical periodicals.

The pharmacists of St. Louis will be urged, through local organizations, to take advantage of the facilities which the library will offer under the new arrangements.

An effort will be made to complete files of the various pharmaceutical periodicals and also to bind the current volumes as they are completed.

DRUGGISTS' CIRCULAR CHANGES EDITORS.

Owing to an affection of the eyes, of constantly increasing severity, Frances B. Hays has been compelled to retire from the editorship of the Druggists' Circular, a position which he has occupied and adorned for many years.

For the present, he will reside at his old home, Oxford, N. C.

Dr. Harry Vin Arny, Professor of Chemistry at the New York College of Pharmacy, has been selected to succeed Mr. Hays as Managing Editor of The Circular.

While we regret the enforced retirement of Mr. Hays, it is a pleasure to know that his work has fallen into the capable hands of

Dr. Arny, who has a host of admirers throughout the country, and especially in Ohio, where he was formerly one of the most efficient workers in the pharmaceutical field.

THE QUALITY OF PRESCRIPTIONS.

Dr. Bernard Fantus, of the College of Medicine, University of Illinois, Chicago, lately undertook an investigation of this subject in the form of a questionnaire. Various pharmacists co-operated by the examination of one hundred consecutive prescriptions each, the total number examined being 10,000.

The results, in percentages, reported by Dr. Fantus are as follows:

To the question, Has the quality of prescription writing improved or deteriorated within the last ten years? 55 percent reported an improvement, and 20 percent a deterioration.

Thirty-six percent. of the prescriptions were written in English, 18 percent were in poor Latin, and 4 percent were barely legible or almost illegible.

Forty-six percent of the prescriptions called for less than three ingredients each and 11 percent for more than five ingredients each; 24 percent were for proprietary remedies, and 11 percent for other specified preparations; 2 percent contained incompatibilities, and 1 percent overdoses and errors.

An extremely small percent of the prescriptions were written in the metric system.

DR. WM. C. ALPERS UNITES WITH CLEVELAND SCHOOL OF PHARMACY.

Dr. William C. Alpers, Chairman of the Historical Section, and well known to the drug trade throughout the United States, has accepted the position of Dean and Professor of Pharmacy of the Cleveland School of Pharmacy, Department of Western Reserve University.

Dr. Alpers is exceedingly well fitted for the position, and all members of the Association will wish him abundant success.

He was born at Hanover, Germany, attended the High School in Hanover, then the School of Technology and later the University of Gottingen, studying Natural Sciences and Mathematics. Came to America and en-

gaged in teaching for nearly 10 years in the St. Matthews' Academy, New York. Attended the New York College of Pharmacy and later took a post-graduate course in chemistry at the University of New York. Was granted the degree of doctor of Science in Chemistry. In 1881 he opened a Pharmacy in Bayonne, N. J., where he staid till 1898. Joined the N. J. State Pharmaceutical So-

DR. WM. C. ALPERS.

cety and was President in 1896, also a member of the State Board of Pharmacy from 1893-98. Became member of the American Pharmaceutical Association in 1890, was Chairman of the Scientific Section in 1896, and Chairman of the Section on Pharmacy and Dispensing in 1905; is now Chairman of the Historical Section, was first Vice President in 1903. After leaving Bayonne, N. J., Dr. Alpers was for a number of years Manager of the Merck Pharmacy, N. Y., and afterwards conducted the Alpers Pharmacy on Broadway and 31st street. He withdrew from active business in 1905. In 1900 he was elected on the Executive Committee of the Revision of the Pharmacopœia and is Chairman of the Sub-Committee on Syrups and Elixirs. Was trustee of the New York College of Pharmacy for three terms till his removal to Cleveland. Contributed for many years to

pharmaceutical and chemical literature, and is now editor of the *Apotheker-Zeitung*, N. Y. Published many pamphlets and two books, "The Medicinal Plants of Staten Island," and "The Pharmacist at Work," Lippincott, 1896. Was appointed Professor of Pharmacy and Dean of the Cleveland School of Pharmacy in 1914.

Dr. Alpers was married to Miss Bertha Guden, who died in 1902, leaving six children, of whom, William H. and Otto, are pharmacists. He married again in May, 1913.

<>

REQUEST FROM THE HISTORICAL SECTION.

To Members of the American Pharmaceutical Association:

Your officers of the Section on Historical Pharmacy issue this appeal to you for contributions to that Section of papers dealing with the history of American pharmacy—personal, general or of some special feature of historic value. It is especially desired that papers on the early history of pharmacy in Michigan and the-Lake states be contributed by those members who have an intimate knowledge of the growth and development of pharmacy and pharmaceutical manufacturing in these states so that the history of the past may be adequately preserved. Detroit is the home of some of the largest manufacturing pharmaceutical firms and should be rich in history of the development of pharmacy and of the origin, study and perfection of many staple pharmaceutical products. Chicago is nearby enough to furnish interesting pharmaceutical history, so are many other cities of the states bordering on the Great Lakes. There are surely many old members who can contribute valuable historical data from their memories and enough younger members who have access to records and papers to make the Detroit meeting one of the richest in historical contributions to the archives of the Association.

It is the intention of the Historical Section to make a special effort to gather historical matter relating to that section of the country where our annual meetings are held. If those members who have helped to make pharmaceutical history would write up their recollections and experiences as contributions to the work of the Association, in a very few years the American Pharmaceutical Association would have in its archives invaluable

data for the future writer of the history of American pharmacy. Papers need not be lengthy nor confined to any one topic, just so that they aid in setting forth the history of some phase of pharmaceutical life and activity.

Your co-operation is earnestly asked in this plan for gathering historical material and its success depends entirely upon a generous response by members to this appeal. However, papers of historic value are cordially invited from members in every section of the country to round out the work of the Section on Historic Pharmacy as a complete presentation of historic data bearing on pharmacy and pharmacists in America. The time to begin writing your paper is *now*. Contributions may be sent either to the Chairman of the Section or to the Secretary, as may be most convenient, the only further favor asked being that they be sent as early as possible so that a programme can be made up for the Section's meetings.

Hoping for a generous response to the Association's request and assuring its thanks in advance to contributors,

Sincerely yours,

WILLIAM C. ALPERS, Chairman.

F. T. GORDON, Chairman.

Proceedings of the Local Branches

"All papers presented to the Association and its branches shall become the property of the Association, with the understanding that they are not to be published in any other publication than those of the Association, except by consent of the Committee on Publication."—By-Laws, Chapter X, Art. III.

Reports of the meetings of the Local Branches should be mailed to the editor on the day following the meeting, if possible. Minutes should be *plainly* written, or type-written, with wide spaces between the lines. Care should be taken to give proper names correctly, and manuscript should be signed by the reporter.

SAINT LOUIS BRANCH.

(February Meeting.)

The Saint Louis Branch of the American Pharmaceutical Association held a regular meeting in the Saint Louis College of Phar-

macy, 2110 Locust street, Tuesday evening, February 10, 1914, with President Wilkerson presiding. After the minutes of the previous meeting were read and approved and preliminary matters disposed of, the program was taken up.

Mr. Arthur C. Schulte read a paper entitled "Windows and Window Dressing," which was printed in full in the March issue of THE JOURNAL. Mr. Schulte's paper was discussed by J. A. Wilkerson, Dr. H. M. Whelpley, O. J. Cloughly, A. W. Pauley, C. T. Buehler, Professor Francis Hemm, Theodore Schwerdtmann, J. W. Mackelden, J. C. Bailey and Julius C. Hoester.

The subject for the next meeting will be a discussion of shorter names and synonyms for some U. S. P. and N. F. preparations.

JULIUS C. HOESTER, Secretary.

<>

NEW YORK BRANCH.

(February Meeting.)

A regular meeting of the New York Branch of the American Pharmaceutical Association was held on the evening of February 12, 1914. President H. V. Arny presided.

The minutes of the previous meeting were read and approved. The treasurer's report was also read and approved.

The Membership Committee submitted the names of two applicants for membership in the parent association.

As Professor W. C. Anderson, chairman of the Committee on Legislation, was absent, Mr. Roemer reported for the committee, calling attention to the provisions of the Town-Blylan anti-narcotic bill, which he indicated if enacted would restrict the sale of all narcotics. He also referred to the Blauvelt Senate Bill No. 5, which confines the sale of bichloride of mercury to prescriptions. The bill also indicates that prescriptions are not to be repeated and no copies of prescriptions are to be given. The drug must be in cubes and colored green.

Dr. Geo. C. Diekman, chairman of the Committee on the Progress of Pharmacy, called attention to the adulteration of oleic acid with paraffin and fish oils. He also gave a method for the detection of oil of sesame in olive oil, an assay method of morphine in tablets and called attention to a false *nux vomica*, which contained no strychnine, as well as a false *buchu*. He also reported on a

sensitive reaction for bromine and on the water absorbing capacity of a mixture of oil of theobroma and yellow wax. The report was discussed by Messrs McElhenie, Raubenheimer, Horstmann and Mayer.

The Secretary announced that he had carried out the instructions given him at the previous meeting by writing the Madison Square Garden Drug and Chemical Exposition that the New York Branch of the American Pharmaceutical Association would not participate in their exposition and that the Madison Square Garden Drug and Chemical Exposition had acted without authority when indicating by advertisement and otherwise that the New York Branch of the American Pharmaceutical Association would co-operate and at the same time indicated that the Secretary of the above named exposition company had acknowledged the letter and complied with the Association's demands, which were to the effect that they immediately discontinue using the Association's name in connection with their exposition.

Dr. Jacob Diner indicated that this incident should prove a valuable lesson to the Association and its members. He stated that individual members should be careful not to involve the Association in commercial enterprises.

John Roemer presented a paper on "Value of Present Methods of Water Analysis in Relation to Disease." He called attention to its many uses as in commerce, manufacture, fisheries, its value and necessity to the existence of man, to the diversity of mineral waters, the disadvantage of hard water in manufacturing, the significance of the purity of our drinking water. The speaker emphasized the extreme sensibility of water tests, both chemical and bacteriological. He indicated that the chemical methods were being supplanted by the bacteriological methods and questioned if the latter gave the clue as to the contamination of water with the typhoid germ; since the test was for the bacterium *coli communis* rather than for the typhoid bacterium. Mr. Roemer referred to two general classes of water, rain water and surface water, and stated that the organic matter in water was of vital concern to the analysis. He described the ammonia and chlorine determination processes. In analyzing water its source should be considered, stated the speaker.

A discussion followed in which Messrs

Diner, Mayer, Niece and Horstmann participated.

Mr. Roemer was formally thanked by the Branch. The meeting then adjourned.

FRANK L. McCARTNEY, Secretary.

CITY OF WASHINGTON BRANCH.

The regular February meeting of the City of Washington Branch of the American Pharmaceutical Association was held Wednesday, February 18, 1914, at the National College of Pharmacy, George Washington University, 808 I street, Northwest, Washington, D. C.

More than thirty members and guests were present at 8:15 when President W. S. Richardson called the meeting to order, and this number was considerably augmented by late arrivals.

The reading of the minutes of the previous meeting was dispensed with, and as no new business was presented, Mr. Richardson introduced Mr. Martin I. Wilbert, of the Hygienic Laboratory, Public Health Service, whose subject was announced as "What the American Medical Association has Done, and What the American Pharmaceutical Association Proposes to do, with Regard to the Patent Medicine Problem."

Mr. Wilbert entered into a general and most enthusiastic discussion of his subject, outlining the history of the growth of the patent medicine business, the efforts of the American Pharmaceutical Association to curb this growth, the efforts of the press to control it, and the manner in which the American Medical Association has dealt with it.

It was pointed out that the American Pharmaceutical Association had, as early as 1853, recognized the evil of the growing patent medicine business and had then adopted resolutions for its suppression. Each passing ten years seemed to revive interest in this subject, but nothing more definite than a number of good resolutions has resulted to the present time.

Judging from the manner of appointment of the present committee, the conditions leading up to its selection, and the attitude of the Association, however, it was stated that it would be unfair to believe the present interest temporary, but, on the contrary, every indication points to the accomplishment of good.

The conditions under which the American

Medical Association undertook its work against patent medicines, and how this work is being carried on, Mr. Wilbert elaborately detailed. A number of the publications of that Association to enlighten the public in this crusade were exhibited and discussed. These were passed around for inspection.

Mr. S. L. Hilton, Mr. J. Leyden White, Dr. F. B. Campbell, Dr. Henry E. Kalusowski, and a number of others feelingly praised the American Medical Association for its stand and pledged themselves to heartily support our Association in its combat against this evil.

The Secretary, Henry B. Floyd, then read a paper covering his observations with regard to the laboratory equipment of local pharmacies. The scarcity of proper reference works, the inaccuracy of scales, weights, graduates, and containers, and the utter lack of sufficient laboratory equipment, was lamented, and the belief was expressed that the only remedy for these conditions rests in a new pharmacy law, by pharmacists, and for pharmacists. Numerous inaccuracies which have caused unthinking, but wholly conscientious, druggists, to be haled into court, were cited, and the avoidance of similar mistakes outlined.

A very vigorous discussion, lasting more than an hour and a half, followed, when the meeting adjourned.

The March meeting will be held March 18, at the College of Pharmacy.

HENRY B. FLOYD, Secretary.

DENVER BRANCH.

The February meeting of the Denver Branch of the A. Ph. A. was held Tuesday evening, February 17th, at the Albany Hotel, the usual dinner preceding the meeting. It had been planned to hold the meeting at Hover's this month and officially open our library, to be known as the Colorado Pharmaceutical Library, but some delay in a shipment of books for the library made it necessary to postpone this event to the March meeting.

Messrs. A. W. Clark, H. C. Washburn, R. H. McKenzie, C. J. Clayton, C. D. Charles, W. T. Hover, S. T. Hensel, L. A. Jeancon, S. T. Kostitch, L. L. Alkire, C. H. Skinner, A. Swoboda, B. F. Seymour, S. L. Bresler, W. W. Grant, W. A. Hover and F. W. Nitardy gathered at the hotel about 6:45 p. m. The

minutes of the January meeting were read and approved. The following resolution was offered:

"Be it Resolved, By the Denver Branch of the American Pharmaceutical Association in regular meeting assembled, that we most respectfully urge the speedy passage by Congress of the Federal anti-narcotic measure, H. R. 6282, known as the Harrison bill."

(Signed) W. A. HOVER, President.
F. W. NITARDY, Secretary.

Mr. A. W. Clark moved it be adopted and a copy forwarded to the United States senators from Colorado. The motion was seconded and carried.

The Branch membership recommendation made by the Secretary in his report at the last meeting was then taken up, the Secretary reading the section of the report referring to the matter, and after short discussion, Mr. Clark moved that the names of the members in question be submitted to the Membership Committee for action, and that the Secretary be guided by their report. The motion carried.

Mr. Nitardy then proposed the creation of an associate membership in the Branch, briefly explaining his objects. A lively discussion ensued, in which considerable opposition was voiced, seemingly on account of a misunderstanding regarding the scope of the proposed associate memberships. On further explanation and discussion, it was decided to create an honorary instead of associate membership, and on motion of Mr. Bresler, Messrs. R. S. Hiltner, chief of the U. S. Food and Drug Inspection Laboratory of Denver, and S. T. Kostitch, pioneer druggist of Denver, were proposed as honorary members. Mr. Hover suggested the inclusion of Dr. William W. Grant in this list and the motion so amended was carried, Messrs. Hiltner, Kostitch and Grant being declared honorary members of the Branch.

President Hover then announced the appointment of the following committees:

Membership Committee—L. L. Alkire, Chairman; L. A. Jeancon, W. T. Hover.

Program Committee—S. L. Bresler, Chairman; L. A. Jeancon, Victor Lagasse.

Committee on Education—Prof. James Seymour, Chairman; S. T. Hensel, Prof. H. C. Washburn.

Committee on Qualifications for Registered Pharmacists—A. W. Clark, Chairman; Emmett Powers, F. J. Lord.

Library Committee—F. W. Nitardy, Chairman; Prof. James Seymour, L. L. Alkire.

Committee on Fraternal Relations—A. W. Clark, Chairman; C. J. Clayton, F. J. Lord.

Committee on Permanent Quarters—Chas. J. Clayton, Chairman; S. L. Bresler, Prof. H. C. Washburn, Hugh SeCheverell.

President Hover then called on Prof. Washburn of Boulder for a few remarks. Prof. Washburn responded with a brief talk touching on the progress of the school of pharmacy and the outlook for the future. Prof. Washburn stated that in the first year of its existence the school had two students, the second year 11 and this year 23. Certainly an excellent showing.

President Hover, before introducing the guest of the evening, stated that he wanted to say a word in regard to the narcotic evil and its remedy and hoped that Dr. Grant would also touch on the subject in his address. He expressed the belief that with the proper co-operation between the medical and pharmaceutical societies and the city authorities the evil could be practically eliminated providing that the city would take steps to care for and treat the unfortunates now addicted to the habit. He believed a policy of this kind, while being at first an expense to the city, would in time mean a saving to the taxpayer, by eliminating a large element that now fills our jails and hospitals and at the same time relieving much suffering and doing humanity a real service. He then introduced Dr. William W. Grant, speaker and guest of the evening.

Dr. Grant responded with an eloquent address, touching at length on the development and objects of the American Medical Association, with special reference to its educational work, its Journal and its Council on Pharmacy and Chemistry. He also touched on the faults of certain members in both professions and some of the unethical practices which prevail. He believed that in time these would be eradicated. His association was working strongly towards that end and with the active co-operation of the pharmaceutical profession more could be accomplished. In regard to the narcotic evil he said he believed his association would be glad to co-operate with our Branch and the combined forces might be able to induce the city to take some action in the right direction. In regard to the pharmacist, he said he had always honored him and he believed that as

a whole our profession was made up of men just as honest, high-minded and sincere in purpose as those of the medical profession. He felt at home amongst them and enjoyed their company.

On closing, President Hover thanked Dr. Grant for his instructive talk, which he felt, would be an inspiration to all. He then asked the opinion of various members on the question of having a committee appointed to meet with or co-operate with the County Medical Society or a committee thereof, in an effort to bring the best influences of the medical and pharmaceutical professions to bear on the city authorities with the object of eradicating the narcotic evil and caring for its present victims.

Messrs. Clark, Clayton, McKenzie, Swoboda and Bresler expressed themselves on the subject, whereupon it was decided to delegate this work to the Committee on Fraternal Relations.

The discussion then turned to a controversy between Parke, Davis & Co. and Dr. Puckner of the Council on Chemistry and Pharmacy of the A. M. A. The majority opinion seemed to favor Dr. Puckner. Elixir Lactopeptin and similar preparations of questionable merit were then discussed. The discussion brought out the opinion that while such products were admitted to be of no therapeutic value, their only service being as a vehicle, their use and demand on prescriptions was nevertheless increasing. The hour being late the meeting adjourned.

F. W. NITARDY, Secretary.

NASHVILLE BRANCH.

On March 12th the regular meeting of the Nashville Branch was held at Furman Hall, Vanderbilt, with Dr. J. O. Burge presiding.

The Committee on A. Ph. A. Home reported that the resolutions adopted by the branch at the last meeting had been presented to the Council for consideration, with the endorsement of the business organizations of Nashville.

The members of the Branch congratulated Dr. J. H. Rogoff on his return from Washington with his bride. His marriage to Miss Fannie Harned took place in Washington, D. C., on February 22d. The ceremony, at the bride's home, being performed by the groom's father.

After a tour of Northern and Eastern cities

Dr. and Mrs. Rogoff came to Nashville, Tenn., their future home.

The bride is the daughter of one of Washington's most prominent citizens. Dr. Rogoff, who has owned several drug stores in Cleveland, O., is now Professor of Pharmacology at Vanderbilt University, Medical Dept.

Dr. E. A. Ruddiman entertained the Branch with the presentation of a number of difficult prescriptions, with criticisms which were freely discussed, a few of which follow:

R Sol. cocaine hyd. 4%.
Sol. adrenalin hyd. aa 1 dram.
Water, q. s., ad 1 oz.

M. Turns red and precipitates after a time. No explanation.

R Tr. iron $\frac{1}{2}$ oz.
Ichthyol 5 drams.
Elix. lact. pepsin q. s., 3 fl. oz.

M. A brown, sticky mass of iron ichthyol sulphate is formed.

R Pot. iod.
Aspirin.
Sod. bicarb.
Tr. iron, aa 5 drams.
Water q. s., 4 fl. oz.

M. Potassium iodide and the tincture of iron liberate free iodine and form some hydriodic acid. The sodium bicarbonate precipitates some ferric hydrate; a fruity odor was observed. CO₂ is liberated.

R Tr. card. co. 1 dram.
Sat. sol. sod. sulph. 4 oz.

M. Half of bottle is solid mass. Alcohol in the tincture throws out sod. sulph.

R Sod. phos. 2 oz.
Pot. bicarb. 2 drams.

M. Mixture becomes damp.

R Acid salicyl. $1\frac{1}{2}$ dr.
Pot. iod. 4 drams.
Water, q. s., 3 oz.

M. Hydriodic acid is formed and iodine is liberated.

W. R. WHITE, Secretary.

<>

NORTHWESTERN BRANCH.

The February meeting of the Northwestern Branch of the A. Ph. A. was held jointly with the Scientific Section of the Minnesota State Pharmaceutical Association in convention assembled at the College of Pharmacy of the University of Minnesota, on February 19, 1914.

After spending three-quarters of an hour inspecting the new building the joint meeting was called to order at 9:45 a. m. by Dean Wulling, chairman of the Scientific Section of the State Association.

Part 1 of the program was completed at the morning session, after which the joint meeting adjourned and the N. W. Branch convened at once to consider the report of the nominating committee for officers for the ensuing year. The following having been nominated were unanimously elected:

President, Mr. C. T. Heller, St. Paul.

Vice-President, Mr. A. D. Thompson, Minneapolis.

Secretary and Treasurer, Mr. E. L. Newcomb, Minneapolis.

Executive Committee, Mr. A. J. Kline, Minneapolis; Mr. F. M. Parker, St. Paul; Mr. W. S. Smetana, Hopkins; Mr. F. A. U. Smith, St. Paul.

Representative to the Council of the A. Ph. A. (for three years), Dean F. J. Wulling, Minneapolis.

Immediately after lunch an hour or more was spent in examining the various educational and scientific exhibits on display, including much of the new equipment of the college.

At 2 p. m. the Scientific Section of the State Association was called to order by Chairman Wulling and brief informal exercises dedicatory of the new buildings were held. At 4 p. m. the joint meeting again convened and part 2 of the scientific program carried out.

The program of the morning and afternoon joint sessions was as follows:

Morning Session.

1. Protect the Interests of the Unfortunate—Mr. John Nielson.

2. The Advantage of Dispensary Practice to Students of Pharmacy—Mr. Oscar J. Bloomo.

3. A New Lime Water Apparatus—Prof. G. Bachman.

4. A Practical Strainer and a Bottle Filler Contrivance—Mr. W. A. Frost.

5. Recreation for Pharmacists—Mr. A. J. Kline.

6. Importance of Food and Drug Chemistry in the U. S.—Mr. C. H. Rogers.

7. Should the Drug Store Experience now Required of Graduates be Dropped?—Mr. H. W. Rietzke.

8. Vegetable Drugs of the Future—Prof. E. L. Newcomb.

9. Historical—Dean F. J. Wulling.

Afternoon Session.

1. Specifications for Buying Chemicals and Drugs—Mr. C. R. Noyes.

2. Some Aromatic Chemicals—Dr. J. S. Brewer.

3. Reports of the College and the Building Committees—Mr. A. J. Kline.

In the first paper presented at the morning session Mr. Nielson made a plea for the better care of those unfortunates who have become addicted to the use of narcotics. He stated he believed that the present narcotic laws in the various large cities and the states were being enforced to a large degree and that the result had been to drive those addicted to the use of habit-forming drugs from the larger cities to the rural districts and hence the subject of narcotic legislation is fast becoming a matter of prime importance to pharmacists of the smaller cities and country districts. Mr. Nielson felt that a record should be kept by pharmacists and physicians of those addicted to the use of narcotic drugs and that the future care and treatment of such persons should be placed in the hands of the members of the State Board of Health. Attention was called to the danger of abruptly cutting off the supply of narcotics from those who are accustomed to their continual use.

Mr. O. J. Blosmo, instructor in charge of the hospital and dispensary drug rooms of the University of Minnesota, stated that both theoretical and practical training are necessary for the acquirement of skill and efficiency in pharmacy. Practical training should consist in part of practice in the manufacturing and dispensing of drugs, preparations and prescriptions to be taken by the patient. Dispensary practice by pharmacy students brings them in close touch with physicians, enabling the students to keep abreast of the rapid advances in the medical profession. From personal experiences Mr. Blosmo felt that a new era in pharmacy had been entered, physicians' prescriptions are written more specifically, fewer patents and proprietaries are used and doctors are more particular in respect to the quality and standard of drugs. Statistics were presented to show the large number of physicians with whom the dispensary student comes in con-

tact and also the number and variety of prescriptions, thus affording the widest possible range of experience. Manufacturing by the pharmacist is emphasized in dispensary practice and the small amount of apparatus usually required is pointed out, as well as the small amount of time required and the financial benefits to be derived. Dispensary practice affords many valuable opportunities which cannot be obtained in other college courses and such training should constitute a part of the instruction given by all colleges of pharmacy.

Prof. Bachman confined his remarks chiefly to the "Preparation and Preservation of Lime Water." From personal observations he stated that he had come to the conclusion that lime water was the most poorly prepared and preserved preparation the pharmacist makes. He stated he knew of a druggist who made his lime water by throwing a pound or more of commercial lime into a two-gallon bottle, filling with tap water and dispensing this for lime water; the bottle was not even provided with a syphon. To further illustrate the lack of care in making this preparation, Prof. Bachman called attention to the pharmacist who makes his lime water when called for, by throwing a tablet of lime into an eight-ounce or pint bottle of water, shaking and selling this cloudy mixture. He further stated that no matter how carefully the selection of lime is made or how well the lime water is prepared, if it is kept in an ordinary container it would soon deteriorate, due to the CO₂ gas in the air precipitating the calcium hydroxide, thus rendering the lime water worthless. A lime water apparatus made according to the drawings of Mr. F. W. Nitardy, of Denver, was fully demonstrated and recommended to the members of the Association as a practical outfit which would solve the lime water problem.

The paper by Mr. W. A. Frost on "A Practical Strainer and a Bottle Filler Contrivance" was listened to with exceptional interest. The use of each apparatus was demonstrated and the speaker stated he had found the appliances of great practical value. The strainer is especially suitable for the rapid straining of thick mucilaginous substances such as quince jelly, elm or flax seed mucilage. This apparatus consists of a rack about twenty inches in height, having a horizontal top provided with an opening in the

center to receive a conical glass percolator of from one and one-half to two gallons capacity. Over the lower orifice of the percolator a muslin bag with a capacity of about a quart is tightly tied. The substance to be strained is poured into the percolator and forced through the muslin bag by pressure with the hands. The advantages of the apparatus were stated to consist of rapid straining with a minimum loss, and a process whereby the preparation is to a large extent protected from contamination by dust, etc. The bottle filling device consisted of an ordinary spring stoppered funnel which was placed in the straining rack above described and over which was inverted the container with the liquid to be bottled. A second rack placed above the first held the inverted bottle in position. By this arrangement a large number of bottles of almost any size could be rapidly and accurately filled.

In discussing "Recreation for Pharmacists," Mr. Kline called attention to a number of activities from which not only pleasure but also profit may be derived. Among the diversions which Mr. Kline had found to be enjoyable and educational, he mentioned the culture of flowers, vegetables, mushrooms and poultry. From the last two hobbies mentioned the speaker stated that he derived a fair margin of profit in addition to the recreation.

Mr. Rogers, in his paper on "The Importance of Food and Drug Chemistry in the United States," pointed out the changes that had been wrought in articles of food and also in the drug trade since June, 1906. He also showed that food and drug chemistry had a direct bearing on the lives and happiness of American citizens. Several instances of note were cited to illustrate how beneficial had been the result of the application of this branch of chemistry. Attention was called to the myriad of remedies which have not as yet been taken up for analysis by the Bureau of Chemistry. The analyses of a number of familiar articles were given, which showed them to be fake preparations. In conclusion, Mr. Rogers heartily endorsed the movement to place upon the statute books of Minnesota an up-to-date pure drug law.

"Should the Drug Store Experience now Required of Graduates be Dropped?" was briefly discussed by Mr. Rietzke. He pointed out the wonderful development of practical courses of instruction in accredited colleges

of pharmacy and the woeful lack of professional experience which the apprentice now receives in many drug stores. The speaker felt, however, that the drug store experience is a most valuable asset, especially when received in a store which reflects the true progress of pharmacy. He believed that pharmacists should give more attention to instructing the apprentice, that the embryonic pharmacist should be encouraged to secure the very best pharmaceutical education possible and that time and help should be offered the student whenever possible.

Prof. Newcomb, in speaking of "Vegetable Drugs of the Future," called attention to the rapid changes for better drugs that have taken place during the last few years. In the past little attention has been paid to the proper methods of collection, packing, transportation, storage, etc., and even today little is known concerning the effects of variations in these factors upon the medicinal value of drugs. Many drugs today are packed in more suitable containers than heretofore used. The nature of the medicinally active principles of drugs was discussed and numerous references were given to show that many of these substances as they occur in the plant are quite unstable compounds and that changes in their composition brought about by fermentation, oxidation, enzyme action, etc., result in products of variable pharmacologic activity. These changes may or may not be desirable. In the proper drying of some drugs it was pointed out that there appears to be a fixation of the medicinally active principles with the protoplasmic constituents of the plant, and that such drugs not only yield to extraction processes readily, but that when preparations made from these are administered, absorption takes place more rapidly than from preparations not so prepared. Tables were presented showing the comparative action of various samples of digitalis as determined by the guinea pig and frog-heart methods, and it was shown that the absorption of the preparation made from carefully collected and dried leaves took place in about 25 percent less time than in any other preparation, and that the total action was above that of any commercial drug tested. Prof. Newcomb stated that if pharmacists are to prepare U. S. P. and N. F. preparations which will yield the action the physician has a right to expect, attention must be paid to all factors which affect even

the innermost nature of the drug. It was suggested that pharmacists give special attention to the twenty-two drugs unanimously passed upon by the U. S. P. IX Sub-committee on Scope. An exhibit of these twenty-two drugs was provided and mention made of the evident good quality of a number. The results of a large amount of work on the drying and packing of drugs was presented and the specimens exhibited.

Dean Wulling's paper dealt briefly with the history of the College of Pharmacy of the University of Minnesota, for whose new building and equipment the legislature and regents appropriated nearly \$110,000 a few years ago. The paper was a preliminary to the pharmacy building exercises which took place early in the afternoon. The paper was supplemented in the later afternoon scientific program by the usual annual college historical paper.

In speaking on "Specifications for Drugs and Chemicals for Medicinal Use," Mr. C. R. Noyes called attention to the numerous grades and varieties of drugs and chemicals which are used for technical purposes, where the requirements are frequently quite different from that of medicine. On account of the great multiplicity of forms and grades of drugs and chemicals, pharmacists should specify definitely what they desire. The speaker felt that drugs of inferior quality for medicinal purposes sometimes find their way to the retail pharmacist, not on account of the desire for cheap products, but through lack of the use of proper U. S. P. names and specifications. The best and safest thing for the retail pharmacist to do when ordering pharmacopœial articles is to specify U. S. P. on every article which is included in that book. Druggists should be cautious about dispensing for medicinal purposes articles bearing the label "for technical use only," and the "so-called" "chemically pure" articles represent a "super-excellence" which is often entirely unnecessary and wasteful for such uses. The Pharmacopœia is a thoroughly practical as well as scientific standard. The requirements in the Pharmacopœia are in almost every case especially suitable for medicinal purposes. U. S. P. chemicals frequently cost no more than technical bulk goods, the quality of which is unknown. On the whole, the pharmacopœial revision committee has laid down standards which are not expensive to comply with. Insist on chemicals labeled

U. S. P., refuse goods labeled with such specifications as "pure," "purified," "white," "medicinal," "redistilled," etc., unless, of course, they are to be used for some purpose other than medicinal. In concluding his paper, Mr. Noyes called attention to specific cases of drugs and chemicals where it is exceptionally important that the U. S. P. grade be used for medicinal purposes.

In introducing the subject "Some Aromatic Chemicals," Dr. J. S. Brewer stated that he was anticipating the requirements of the retail drug trade by two or three years, but many of the substances which he desired to call attention to were already in demand on account of the high price of natural raw materials. The magnitude of the synthetic perfume industry was illustrated with photographs of several Swiss and German factories showing both exterior and interior views which afforded an excellent idea of the expensive apparatus necessary to produce this class of oils. From a very small beginning and the production of a comparatively few articles, the manufacture of aromatic perfume materials has reached enormous proportions and now forms a very important part of the chemical industries of the world. The speaker gave a practical demonstration of the similarity of odor between the synthetic and natural products, showing samples of oil of rose, true and synthetic, oil of neroli, true and artificial, and the two varieties of oil of jasmine. Commercial varieties of these artificial oils are mostly mixtures of certain chemicals, and percentage composition formulas were given which would enable one to prepare, at a very reasonable cost, all three of the oils mentioned. In connection with oil of rose, it was stated that not a drop of the true article was now being brought into the country, that the ultimate consumer could not afford to pay the price that would have to be charged for a pure article and that the purchaser simply wanted what he paid for. Samples of so-called oil of rose were shown which contained a large percentage of geraniol and phenyl-ethyl-alcohol and which would still congeal at a reduced temperature on account of reinforcement with a stearopten. It was clearly shown that by clever manipulation the specific gravity, rotation and other characteristics of oils could be so adjusted as to make many of them answer to most of the prescribed tests. The chemistry of the manufacture of synthetic violet oil or

Ionone was discussed at some length and illustrated with samples of both the alpha and beta varieties. By reason of the expiration of certain patents and on account of new processes coming into use, the price of this article is now within the reach of all and the writer recommended its use in perfuming the ordinary toilet creams and in the manufacture of perfumes, toilet waters and lotions, such as are frequently made in the drug store. The following basic aromatic chemicals were discussed and samples shown to demonstrate the character and perfume strength: Alcohol Cinnamyl, Anisic Aldehyde, Benzyl Benzoate, Benzyl Acetate, Geraniol, Citronnellol, Citral, Jacinthe, Iso-Eugenol, Phenyl-Ethyl-Alcohol and Methyl-Heptin-Carbonate.

EDWIN L. NEWCOMB, Secretary.

CHICAGO BRANCH.

The March meeting of the Chicago Branch of the American Pharmaceutical Association was held on the evening of March 17th. An illustrated lecture on the "Production of Diphtheria Antitoxin" was delivered by Dr. H. M. Letton, of the Research Laboratory of Parke, Davis & Co. The meeting was well attended, about one hundred members and guests being present.

Dr. Letton displayed with the lantern fifty very fine views fully illustrating each important step in the process of preparing antitoxin. His lecture, remarkable for its clearness and interesting detail, was very favorably received.

The lecture was followed by a discussion which included not only diphtheria antitoxin but also the present therapeutic status of antitetanic serum, typhoid vaccine and other serum products.

The meeting adjourned with a hearty vote of thanks to Dr. Letton for his courtesy to the Branch.

F. N. GATHERCOAL, Secretary.

PHILADELPHIA BRANCH.

At the March meeting of the Philadelphia Branch A. Ph. A. the following officers were elected, to serve during the ensuing year:

President, Prof. E. Fullerton Cook; First Vice-president, Samuel C. Henry; Second Vice-President, Prof. J. W. Sturmer; Secretary, Dr. R. P. Fischelis; Treasurer, Mr. M. M. Osborne.

Committee on Practical Pharmacy: Prof. Charles H. LaWall, Chairman; Mr. W. W. McNeary, Mr. A. Hunsberger.

Committee on Professional Relations: Mr. W. L. Cliffe, Chairman; Mr. F. M. Apple, Dr. F. E. Stewart.

Committee on Membership: Mr. A. J. Staudt, Chairman; Mr. William E. Lee, Mr. Quintus Hoch.

The report of the Treasurer indicated a comfortable balance on hand.

The scientific program of the evening consisted of a contribution by Mr. Franklin M. Apple, entitled: "Indispensable Insurance for Pharmacists." Mr. Apple's paper brought out an interesting and lengthy discussion participated in by Messrs. LaWall, Cliffe, Cook, Henry, Osterlund, Sturmer, and others.

AMBROSE HUNSBERGER, Secretary.

PITTSBURGH BRANCH.

The meeting of the Pittsburgh Branch held Friday evening, March 13, was honored by the presence of Richard H. Lackey, of Philadelphia, president of the Pennsylvania Pharmaceutical Association, who was an interested participant in the proceedings.

President Lackey was given an opportunity to urge all those present who were not members of the state body to affiliate, especially would it be a fitting manner for the pharmacy students present to thus start their pharmaceutical career right by early identifying themselves with that useful, militant body of pharmacists.

The secretary suggested that the Branch invite Geo. B. Parker, Esq., whose handsome lantern slide exhibit and talk covering the wild flowers of Pennsylvania, was so entertaining a feature of our last meeting, to attend the 1914 meeting of the State Association and present his interesting and instructive entertainment for the benefit of those present from other sections of the state. A motion to that effect was made by Dr. J. A. Koch, and warmly supported by Dr. A. F. Judd, and the motion prevailed. The secretary was instructed to interview Mr. Parker and endeavor to have him accept the invitation.

Dr. Louis Saalbach in a review of the proposed changes with new standards and descriptions submitted by the Revision Committee of the U. S. Pharmacopoeia, criticized the method suggested for testing the purity

and genuineness of salicylic acid, which, he claimed, is not a good method for distinguishing the natural product from the synthetic, and looks as though it will result in putting a premium upon adulteration. It will be a very easy matter to so prepare the synthetic product as to have it respond to the test proposed to determine the genuine article.

Dr. Blumenschein said: It looks very much now as though the output of natural salicylic acid, so labelled, is greater by far than the supply of oil wintergreen can possibly produce, so one can draw his own conclusions.

The status of bichloride of mercury in the face of the deluge of proposed legislation that it is being subjected to, was discussed, the subject being opened by B. E. Pritchard, who presented numerous editorial comments from various leading pharmaceutical journals bearing upon the absurdity of the prominence that is being given to that one particular toxic drug, both by the press and the legislative bodies of many states and the United States.

Mr. Lackey said: The enormous sale all over the country of bichloride tablets for the plainly understood purpose of preventing conception demands some effective legal method for its being stopped. Do we as reputable pharmacists want to put ourselves on record as willful purveyors of the article for that purpose? It is our plain duty to use every means in our power to make it as difficult as possible for the public to obtain these dangerous tablets.

Dr. Saalbach submitted a specimen of leaves of absorbent paper saturated with a solution of bichloride of mercury and so graded as to make it possible to readily prepare a solution of bichloride of a definite percentage, which can be used to replace the widely sold tablets, and thus by curtailing their sale make both criminal and accidental use of the tablet less prevalent. On motion the Branch put itself on record as favoring the universal use of the saturated paper leaf form and as opposed to the continued use of the dangerous tablet form of bichloride of mercury. Dr. Darbaker suggested, and the suggestion was on motion adopted, that the sheriff and coroner be notified of the adoption of the resolution adopted.

Dr. Saalbach submitted a specimen prescription for the purpose of indicating how extremely careless some physicians are con-

cerning the dangerous character of bichloride, as follows:

℞ Hydrag. chlor. corros. one drachm.

Sodii chlor. one ounce.

Div into 12 powders. Sig—Use as directed.

Dr. Koch said, it was for the purpose of trying to reach some wise method to recommend in the securing of proper legislation that will not be too far reaching in character to restrict the distribution of bichloride tablets that had impelled the selection of the subject for discussion before the Branch.

The secretary called attention to the Act passed by the last session of the Pennsylvania legislature, hurriedly drafted and rushed through both houses in five days, that Governor Tener, at his request, had refused to sign, because it was so drastic in its provisions that it would have legislated the drug itself clear off the map, which would be a senseless thing to do.

The Pharmacist and the Law

ABSTRACT OF JUDICIAL DECISIONS.

SELLING WRONG MATERIAL—CONTRIBUTORY NEGLIGENCE. A dairyman sued a druggist for negligently delivering to the plaintiff five pounds of common salt in lieu of five pounds of Epsom salt, as ordered, which, as alleged, proximately caused the death of the plaintiff's cow to which he administered a dose of it—two pounds, as the evidence showed. The defendant pleaded contributory negligence. On appeal from a verdict and judgment for the plaintiff, it was held that whether or not the defendant was guilty of error or negligence in supplying the plaintiff with an article radically different in fact from the article ordered, and whether or not that negligence, if found, proximately produced the untimely demise of the plaintiff's cow, were disputed questions of fact to be determined by the jury. But that the plaintiff was himself guilty of the grossest negligence, which was immediately productive of the animal's death, was a clear conclusion of law from which there was no escape.

There is no confusing similarity in the appearance of common salt and Epsom salt.

Both are household articles in common use, and more or less familiar to all men of ordinary intelligence and experience. Moreover, the plaintiff was a dairyman of long experience, and quite familiar with the use of both articles in the course of his business. He was skilled in the art of bovine healing by a practice of 30 years upon his own animals, and he habitually administered to them Epsom salt for the relief of those digestive disorders to which they were frequently subject. He saw and intimately handled this salt, which was not labeled Epsom salt, and which was in a bag showing on its face that it came from the defendant's "seed and dairy" store, a separate and distinct branch of its business, from which the plaintiff customarily bought his butter salt for use in his dairy. It was not at all like Epsom salt, and on his cross-examination, the plaintiff demonstrated his ability to readily distinguish it from that article.

"The ordinary conduct of rational beings," said the court, "must be governed by common prudence and common sense, and he who fails in this to his own hurt cannot justly charge the ills that follow to the antecedent and remote fault of another, albeit such remote fault supplies the condition without which the injury would not have occurred. The result here complained of was plainly due to the inexcusable carelessness and folly of plaintiff, and to allow him to recover damages from defendant under the circumstances shown would certainly insult the common sense of mankind. The verdict of the jury was contrary to the law and the evidence, and should have been set aside by the trial court on the motion of defendant."

It was also held that the instance of a man who "swallowed a pound of salt in a pint of ale, and died in a few hours, with all the symptoms of irritant poison," read from a medical book, was fundamentally illegal and inadmissible as evidence in the case.—*Gorman-Gamili Drug Co. v. Watkins*, *Alabama Supreme Court*, 64 So. 350.

INTOXICATING LIQUORS—WRONGFUL SALE BY DRUGGISTS—SPECIAL PENALTY. On an agreed statement of facts in proceedings against a druggist for selling liquor without a West Virginia State license as a druggist, it was admitted that the accused had not a state license for the sale of intoxicating liquors; that he sold a person a pint of whiskey; that

he was then a licensed druggist, and that the purchaser of the whiskey had no prescription of a physician therefor. The accused maintained that he could not be prosecuted as an ordinary seller of intoxicating liquors without a state license, but only as a druggist, as to whom a lighter penalty is prescribed.

A druggist, said the court, is merely an accepted person under the general law prohibiting sales of intoxicating liquors without a state license. When he does not sell intoxicating liquors in the only way that the exception in his favor permits him to sell them, he is a violator of the general terms of the West Virginia statute which says that no one without a state license shall sell them. When in making a sale a druggist does not comply with the restrictions of the exceptions in his favor, he is simply one selling without a state license. By the exception he may sell alcohol for mechanical or scientific purposes, or alcohol, spirituous liquors, wine, porter, ale, beer, and other intoxicating drinks for medicinal purposes on the prescription of a reputable physician. But if he sells any of them otherwise, unless he had a state license therefor, he brings himself within the general terms of the statute which prescribes that no person without a state license shall sell them. He may then be indicted and proceeded against just as other persons selling without a state license. But the West Virginia Legislature has prescribed a lesser penalty for an unlawful sale of intoxicating liquors by a druggist than for such a sale by an ordinary seller. Code 1906, ch. 32, secs. 3 and 5. Formerly it was not so, but the reverse. *State v. Cox*, 23 W. Va. 797. Therefore, if the evidence establishes that the accused at the time of the sale was a druggist and unlawfully sold as such, only the lesser penalty imposed for such special offense can be inflicted.—*State v. Wills*, *West Virginia Supreme Court of Appeals*, 80 S. E. 783.

SUB-STATION ACCOUNTS. Marcus Sachs and his son, Simon Sachs, became partners in the drug business. This continued for a number of years when, it appeared, Simon Sachs sold the partnership and formed a corporation, doing the same business as had been done by the partnership. During the partnership Simon Sachs was appointed a deputy clerk for the sale of postal money orders, with a branch station in the firm's drug store. Each day he deposited the moneys re-

ceived from the sale of postal money orders in a bank. The checking account with the bank was in the firm name, but the deposits were made with two deposit slips, one showing the receipts from the sale of postal money orders, and the other the total amount of deposits of the drug store business and of sales of postal money orders. The account was kept by the bank in this manner, the deposits of postal order receipts being kept in a separate account under the heading "Station Receipts." Each day Simon Sachs made a report of the sales of money orders to the postmaster, and attached thereto a check to the postmaster's order on the bank for the money deposited as "Station Receipts" for the period covered by the report.

Marcus Sachs filed a bill alleging misapplication of the partnership funds by Simon Sachs, and obtained the appointment of a receiver of the corporation, who took possession of the funds deposited in the bank about April 12, 1911. Subsequently the postmaster filed a petition, setting forth, among other things, that Sachs made his daily report for April 10, 1911, showing sales of money orders to the extent of \$678.84, and delivered a check payable to the postmaster for that sum, dated April 11, and a daily report for April 11 showing sales to the amount of \$300.24, and a check for that sum dated April 12; and that, on presentation of these checks to the bank, payment was refused. He prayed for an order that the money represented by the checks be paid. Simon Sachs also presented a petition to the same effect.

At the hearing of the case it appeared that the receiver had taken possession of \$494.04 of the money on deposit in the bank. As stated by a witness, the bank had apparently peremptorily taken five or six hundred dollars of the balance of the deposit to apply on some note. The receiver was ordered to pay over to the postmaster the money turned over to him by the bank. There was no mingling of the money deposited from the sale of money orders and from the drug business. The bank kept the former in a separate account, designated as "Station Receipts." The bank's account was, in substance and essence, with the postmaster, and the adoption of a convenient method of checking it out under the firm name did not change the substance of the transaction.—*Sachs v. Sachs*, 181 Ill. App., 296.

IMPLIED WARRANTY OF MANUFACTURE. A manufacturer is liable only to his immediate vendee for breach of an implied warranty as to the merchandise manufactured by him, as his liability depends upon privity of contract; but exceptions exist where injury is caused by something noxious or dangerous, or where the manufacturer practices fraud or deceit, or is negligent with respect to the sale or construction of a thing not immediately dangerous. "Within one of the exceptions is to be found the reason for holding the manufacturer of patent or proprietary medicines to answer at the suit of the ultimate consumer. Direct actions are allowed in such cases because the manufacture of medicine is generally shrouded in mystery, and sometimes, if not generally, they contain poisons which may produce injurious results. They are prepared by the manufacturer for sale and distribution to the general public, and one purchasing them has a right to rely upon the implied obligation of the manufacturer that he will not put in ingredients which if taken in prescribed doses will bring harmful results. Reference may be had to the following cases which sustain, and in which many other cases are cited which sustain, this exception: *Thomas v. Winchester*, 6 N. Y., 397, 57 Am. Dec. 455; *Blood Balm Co. v. Cooper*, 83 Ga. 457, 10 S. E. 118; *Welsor v. Holzman*, 33 Wash. 87, 73 Pac. 797, 99 Am. St. Rep. 932."

Another exception, it is now said—the doctrine is comparatively recent—is referable to the modern method of preparing food for use by the consumer, and more general and ever increasing use of prepared food products. A manufacturer of food products under modern conditions, it is held, impliedly warrants his goods when dispensed in original packages, and such warranty is available to all who may be damaged by their use in the legitimate channels of trade, including those who purchase them for resale, as well as the ultimate consumers. The violation of the pure food law by a manufacturer of foods products is evidence of negligence in the preparation and sale of such food, and it is available in a suit by a middleman, as well as by a consumer.—*Mazetti v. Armour & Co.*, *Washington Supreme Court*, 135 Pac., 633.

SALE OF OLEOMARGARINE—SELLING OR GIVING AWAY COLORING MATTER. An inspector of the Agricultural Department purchased from a retail grocer in New York State a

one-pound print of oleomargarine, with which he was given a capsule of coloring matter, conceded to be a harmless vegetable compound. In an appeal from a conviction of a violation of the New York Agricultural Law, the sole question was the validity of Section 41 of the statute, providing that "no person selling any oleaginous substance not made from pure milk or cream of the same as a substitute for butter, shall sell, give away, or deliver any coloring matter" is valid. It was held by the Court of Appeals that the provision was a constitutional and valid enactment within the police power of the State. —*State v. Von Kainpen* (decided March 3, 1914).

Obituaries and Memorials

Persons having information of the death of members of the A. Ph. A. are requested to send the same promptly to J. W. England, 415 N. 33d St., Philadelphia, Pa. Information as to the age, activities in pharmacy, family, etc., of the deceased should be as complete as possible. When convenient a cabinet photograph should accompany data.

JAMES G. STEELE.

James Gordon Steele, pioneer of California and leader in pharmacy on the Pacific Coast, died at his home in San Francisco on Monday, February 2, 1914, at the age of 76 years and 38 days. His end was peaceful and wholly unexpected. On the morning of the second of February Mr. Steele arose cheerful and happy as usual. The day being beautiful, he took a long walk, returning refreshed, even expressing a desire to go for another stroll, but acting on the suggestion of his wife, he took a book on music, sat down in a chair, and when Mrs. Steele entered the room a few minutes later she found him dead, head slightly inclined, book still in his hands. Remarkably enough, Mr. Steele wrote his autobiography two weeks before his death, a portion of which is used in the preparation of this sketch.

Mr. Steele was born in Boston, Mass., December 25, 1838. He completed the studies of the grammar schools, and two years of high school. He came to California at the age of 15 and entered the employ of George

C. Shreve and later that of his uncle, Wm. W. Keith. He proved a trustworthy helper and Mr. Keith placed him in charge of one of his drug stores. He studied chemistry under Dr. Raymond, who had taught chemistry in the Cincinnati College of Pharmacy, and botany under Dr. Kellogg, the well-known curator and librarian of the California Academy of Sciences.

Mr. Steele was largely instrumental in organizing the California Pharmaceutical Society in the year 1868. In 1878 he gave up the retail drug business and devoted himself to supplying the Eastern and European market with California crude drugs, but in 1880 he again opened a retail store largely devoted to prescription work. In 1895 he was made city chemist of San Francisco, which position he held for two years. He became a member of the American Pharmaceutical Association in 1859, in which organization he was always active and contributed several papers to the proceedings, one on "*Grindelia robusta*" and one on the "Drug Market of San Francisco," which also contained a list of California medicinal plants; another paper was on "The Pines of California."

Mr. Steele was also an active member in the newly organized California Pharmaceutical Association, attending its meetings and contributing several pages of historical interest. A very full history of the California College of Pharmacy was completed shortly before his death. When the old California Pharmaceutical Society decided to establish a college of pharmacy in 1874, Mr. Steele, with W. T. Wenzell, W. M. Searby, J. W. Forbes, John Calvert, Mr. Simpson and Mr. Mayhew, were appointed a committee with power to incorporate such a college, becoming the first trustees of the California College of Pharmacy.

Mr. Steele was a most enthusiastic botanist, devoting much time to the study of the flora of California. In 1876 he sent 50 different species of California medicinal plants to the Philadelphia College of Pharmacy, at which time his intimate friend, Prof. Maisch, was instructor in materia medica in said college. Mr. Steele was essentially a student of books, of nature, of people. He was possessed of a most genial nature and a kindly disposition. He made many warm friends. His favorite author was Shakespeare, from whom he quoted freely. His favorite recreation was music, being a performer and composer of

considerable ability. It was this fondness of music which brought him in touch with the late Winchell Forbes.

The following intimate friends of Mr. Steele have preceded him by a few years or less: W. M. Searby, John Calvert, J. McDonnell, W. T. Wenzell and H. H. Behr, all from San Francisco. Each one of the men named represents a distinct landmark in the progress of pharmacy on the Pacific Coast.—*The Pacific Pharmacist.*

Council Business

COUNCIL LETTER No. 13.

Philadelphia, Pa., March 6, 1914.

To the Members of the Council:

The following communication has been received from Hugh Craig:

"I have perused with a great deal of interest Council Letter No. 12, dated February 19. The matter with which it has to do is one to which I have given a great deal of attention during the past four or five months, and the result of my consideration of the subject is not such that leads me to agree with President Beringer that a specific shape for tablets of corrosive mercuric chloride will afford the desired relief. Investigation carefully conducted by the New York Board of Health shows that out of all the deaths from this poison reported during the period of ten months in that city all but about 5 percent or 6 percent were suicidal. It is folly to expect an intelligent person to believe the reports of accidental poisoning with this substance as they appear in the daily papers. Who, for instance, ever heard of any one taking *four headache wafers dissolved in water*? Yet we are told by the press that four 'bichloride' tablets were dissolved in a glass of water by a woman and taken in mistake for headache wafers! These misguided folk who wish to rid themselves of the troubles of existence and the world of their troubled existence will adapt a coffin-shaped tablet just as readily as they will a round one. The shape of the tablet has nothing to do with the desired effect.

"As far as children are concerned, they cannot tell the word 'poison' on the tablet from the motto on the popular candy wafers so dear to the childish heart. Neither can they tell whether a coffin-shaped object is poisonous or is merely a round wafer with some of the edges broken off.

"In my opinion it is a waste of time and energy to attempt to regulate the misuse of mercuric chloride by endeavoring to formulate a restriction as to the shape of the tablet into which this substance is compressed.

The real means of reaching the crux of the situation is the restriction of the sale of this substance to physicians' prescriptions. Despite the wide popular demand for the handy tablet, which can be purchased in any department store, there will be no injury to anybody if all are required to get this drug through real restrictive channels. Restrictions should also apply to physicians who are very likely to leave three or four of these poisonous tablets wrapped up in a prescription blank on the table in a sick room and also to veterinary surgeons who dip them out by the handful and leave them with oral directions for their use with an ignorant stableman—yet these stablemen being of a little sensitive nature and more stolidly constituted, seldom eat these tablets in mistake for an after-drink breath perfume or a chew of tobacco!

"There is another side to the question contained in Letter No. 12 and that is, of the advisability of the Association's taking over any such proposition. While it might be possibly easier to over-estimate the influence such an action would have upon the consideration given to the Association by those who are at present engaged in the manufacture of these tablets in various shapes, this phase should not be lost sight of. This matter, I believe, can be dealt with, very satisfactorily by some of those who have a longer acquaintance with the Association and its purposes. To me it appears rather a departure for the Association to engage in the manufacture of or the supervision of the manufacture of any article of commerce—I have not, in making this statement, lost sight of the fact that the Association publishes the National Formulary.

"There was not enclosed with the letter any voting card, and there was nothing about the letter which leads me to believe that a vote is to be taken at this time, but rather the matter is simply up for discussion. However, if a vote is expected, I should like to have mine recorded in opposition to the proposition."

President G. M. Beringer replies to Mr. Craig's comments, as follows:

"I have read with great interest the comments of Mr. Hugh Craig on Council Letter No. 12. I fear that Mr. Craig fails to grasp the real situation presented in that Council Letter. I agree with him fully as to the necessity of educating the public to the importance of exercising the proper care in the handling of all poisons.

"The question of an official shape for tablets of mercuric chloride is only one of the means of safeguarding the careful handling of these tablets, and it was not presented as the sole means that should be adopted. Through the clamor of the public press, the legislators of the country are very likely to enact in the various States and Congress, some form of legislation that shall define a shape for bichloride tablets and the proper precautions regarding labeling and selling of

these. This is evidenced by the bills that are now pending in Congress and in several of the state legislatures. Of all the shapes that have so far been proposed, there is none for originality and distinctness of character that is at all comparable with the proposition of a coffin shape tablet. As the latter form has never been used for foods, confections or harmless medicines, it has that distinct advantage of novelty and individuality, and its use could very readily be restricted solely to toxic tablets for external application without proving detrimental to manufacturers of other products.

"The desirability of this shape for bichloride tablets appealed to Vice-President Apple and President-elect Mayo as well as to myself. It is apparent, however, that if this shape is to be monopolized by a patent controlled by any one manufacturer, no matter what benefit might accrue to the public from this safeguard, it could not be endorsed by either the Association or the U. S. Pharmacopœia. The proposition presented in Council Letter No. 12 by which monopoly could be prevented and every honorable manufacturer be given the privilege of making such a standard tablet, was the only plan that appeared to be feasible to assure the public of the greatest amount of benefit and safety.

"In presenting this plan to the Association, we were quite aware that this was a departure from the usual line of activity of the American Pharmaceutical Association, but I conceived that it is well within the scope of usefulness of the Association to thus exert its influence for the benefit of the public. If the American Pharmaceutical Association will not accept this unusual opportunity, then, no doubt, the Norwich Pharmacal Co. will prosecute their patent to completion and monopolize the manufacture of such tablets in the United States.

"Mr. Craig is certainly in error in stating that "after a careful consideration of the question from every possible view point, the Association is opposed to any provisions of the U. S. Pharmacopœia or National Formulary prescribing the shape, size or color of mercury bichloride or other poisonous tablets, or shape, size or color of the package in which they shall be furnished." The Committee of Revision of the U. S. Pharmacopœia have already, by vote, decided to introduce a bichloride of mercury tablet, and as many of the members of that Committee of Revision are likewise members of the American Pharmaceutical Association, such a statement coming officially from the Association would be inconsistent. Some of the foreign pharmacopœias and formularies have fixed standards of bichloride of mercury tablets, and the U. S. Pharmacopœia in fixing a standard for bichloride tablets will simply follow precedents already set in other pharmacopœias. We need not necessarily adopt standards and shapes that were adopted in other countries, but well may fol-

low the most advanced American thought for an American standard.

"I hope that Mr. Craig will modify his resolutions so as to make them entirely consistent with the real view of the Association. May I likewise point out the inconsistency of his objection to a uniform shape for poison tablets and then to propose a special receptacle as a container for all poisons."

Secretary J. H. Beal writes that he is heartily in favor of taking over the assignment of the patent which it is hoped will be obtained by the Norwich Pharmacal Company; also, that the patent should be accepted by the Association as a trust, and its free use to the medical and pharmaceutical professions permitted without charge and without restrictions, further than necessary to prevent the use of the design for confections and harmless medicaments. He offers the following resolutions, which are seconded by G. M. Beringer:

"(1) *Resolved*, That the American Pharmaceutical Association accept the complete assignment of the patent-rights of the Norwich Pharmacal Company in and to a design patent for a poison tablet, serial number 801,748, as tendered by the said Norwich Pharmacal Company in their communication to the President of the Association, dated February 16, 1914, and presented in Council Letter No. 12.

"(2) *Resolved*, That the American Pharmaceutical Association hold such design patent exclusively for the free use of the medical and pharmaceutical professions of the United States, without restrictions except such as may be necessary to prevent possible abuse through use of the design for confectionery or other non-poisonous substances.

"(3) *Resolved*, That the American Pharmaceutical Association hereby tenders to the Norwich Pharmacal Company a vote of thanks for their generous and public spirited proposition."

The above will be regarded as *Motion No. 25 (Assignment of Patent-Rights for Poison Tablet.)*

The following communication has been received from F. W. Nitardy:

"In his address at Nashville, President Day recommended that a portion of the annual dues from members of local branches be remitted to the branch treasurer. The committee on the President's address referred the matter to the Council for action.

"I believe President Day's recommendation is a valuable one, one that will work to the benefit of both the national body and the branches, and one on which early action by the Council would be advisable.

I shall appreciate it if you will submit the subject to the Council for discussion or vote together with my argument based on the experience of the Denver Branch.

"Our branch is very active. It has gained some seventy-five new members for the A. Ph. A., holds regular and well attended meetings, which in turn are responsible for quite a number of members retaining their interest in the A. Ph. A. In order to maintain such a branch more or less money is needed. It may be raised by assessing each member several dollars yearly in local dues, but this frequently acts as a stumbling block in gaining and holding members. We have contented ourselves with yearly local dues of \$1 with a result that a deficit occasionally exists in our treasury. This has from time to time been quietly wiped out by some of our more prosperous and generous members. Our greatest handicap has always been lack of money. The local branch carries all of the burden, while the benefits of its existence are without question shared by the national body. Every city in the U. S. with a population of 100,000 or over could support a good local branch and do it better if it could obtain a little financial help from the national body. If branches would be established in all communities as large as Denver or larger, the membership of the A. Ph. A. would increase very materially, and what is more, we would have something substantial to help hold the interest of new members, especially such as cannot attend the annual conventions, of which there are many.

"If the national treasurer could remit \$1 yearly of the dues of any branch member paying not less than \$1 yearly local dues, on request, to the local branch treasurer at the end of the fiscal year, providing such request is accompanied by a list of dues-paid branch members and a copy of the treasurer's report covering the year in question, a substantial aid would be rendered, at the same time protecting the national body against paying out any money for which it could see no returns.

"In case a scheme like that outlined above meets the approval of the Council, I should like to move its adoption.

"Now, in regard to Council Letter No. 12. I have read very carefully the letter, also the bulletin on "The Sale of Bichloride Tablets" by Martin I. Wilbert (Reprint 151—Public Health Reports) and believe President Beringer's recommendation is a step in the right direction towards solving the bichloride problem and heading off unwise legislation in the matter.

"If it has not already been done, I move the acceptance of the very generous offer of the Norwich Pharmacal Co., also, that we tender them a vote of thanks and that notice of this action be sent to the pharmaceutical press."

The following communication has been received:

Nashville, Tenn., Feb. 25, 1914.

Why the A. Ph. A. Home Should Locate in Nashville, Tenn.

WHEREAS, At the last annual meeting of the A. Ph. A. held in this city the proposition to provide a permanent home for the Association was referred to the Council for future consideration; and

WHEREAS, Efforts are now being made by other cities to secure the location of this permanent home.

Therefore, We, the members of the Nashville Branch, respectfully submit for the consideration of the Council, the following reasons why the home should be located in Nashville, Tenn.:

(1) Because Nashville offers a free site for the home.

(2) It is about the center of population of the U. S. and within 24 hours' travel for the great majority of the pharmacists of the United States.

(3) The climate is unexcelled for the proposed botanical gardens.

(4) Has the second largest facilities in the U. S. for printing.

(5) Is the greatest educational center in the Central-Southern States and one of the greatest in the entire United States.

(6) Has progressive pharmaceutical schools for both races.

(7) Has a live growing A. Ph. A. Branch.

(8) Affords ample hotel facilities for future A. Ph. A. conventions.

(9) Has low freight rates, proximity to needed supplies considered.

(10) Incorporated bodies for educational purposes on a non-profit basis are not liable for taxation.

(11) Has been proven to have the cheapest cost of living of any city in the U. S.

Respectfully submitted,

W. R. White,
S. C. Davis,
Ira B. Clark,

Committee.

The above resolutions were adopted at the last meeting of the Nashville Branch of the Association.

Nashville Branch, A. Ph. A.,

J. O. Burge, Ph. G., President.
Williams R. White, Secretary.

We, the undersigned commercial organizations representing the entire business interests of Nashville, Tenn., do hereby heartily endorse the above resolutions and invite the American Pharmaceutical Association to locate its home in our city.

The Nashville Industrial Bureau,

J. M. Gray, Jr., President.

A. P. Foster, Secretary.

The Nashville Business Men's Association,

M. S. Ross, President.

J. R. Beesley, Secretary.

J. W. ENGLAND,

Secretary of the Council.

UNITED STATES PUBLIC HEALTH SERVICE.

List of changes of stations and duties of commissioned and other officers of the United State Public Health Service for the period ending March 17, 1914:

Rucker, W. C., Assistant Surgeon General. Directed to proceed to Chicago, Ill., for the purpose of attending the annual mid-winter conference of the American Medical Association on Public Health, Legislation and Medical Education, February 23-24, 1914. Also designated as the Service representative on the National Legislative Committee of the American Medical Association. Also directed to deliver an address on "Public Health Legislation" before the Federation of State Medical Boards of the United States, February 25, 1914, and on "Common Sense in Public Health Administration" before the Chicago Medical Association, February 25, 1914. February 19, 1914.

White, J. H., Surgeon. Granted 1 month and 7 days' leave of absence from March 11, 1914. Granted 10 months and 23 days' leave of absence, without pay, from April 18, 1914. February 24, 1914.

Cobb, J. O., Surgeon. Granted 1 day's leave of absence, February 15, 1914, under paragraph 193, Service Regulations. February 14, 1914.

Cumming, H. S., Surgeon. Detailed, at the request of the President of the Maryland Conservation Association, to deliver an address on "The bearing which the pollution of tidal waters has on health," at Johns Hopkins University, February 25, 1914. February 19, 1914.

Lavinder, C. H., Surgeon. Detailed, at the request of the State Commissioner of Health of Virginia, to deliver a lecture on pellagra, at the Medical College of Virginia at Richmond, February 24, 1914. February 19, 1914.

Lumsden, L. L., Surgeon. Detailed, at the request of the President of the Maryland Conservation Association, to deliver an address on "The value to Maryland of controlling waterborne diseases," at Johns Hopkins University, February 25, 1914. February 19, 1914.

Sweet, E. A., Passed Assistant Surgeon. Detailed to make as complete studies as practicable of the migration of tuberculous per-

sons in New Mexico in interstate traffic. February 20, 1914.

Krulich, F., Passed Assistant Surgeon. Relieved from duty at the San Francisco quarantine station and directed to report to Surgeon Woodward for duty at the Exposition Hospital. February 24, 1914.

Ruoff, J. S., Assistant Surgeon. Relieved from duty at Ellis Island, N. Y., and directed to report to the medical officer in charge of the Marine Hospital, Stapleton, N. Y., for duty and assignment to quarters. February 18, 1914.

Phelps, E. B., Professor of Chemistry. Directed to proceed to Chicago, Ill., for the purpose of making necessary preliminary surveys in connection with investigations of the pollution of navigable waters. Also to proceed to Cincinnati, Ohio, for conference with officer in charge of Service investigations, stopping enroute at Indianapolis, Ind., for conference with the Secretary of the House Board of Health, relative to pollution of the Ohio river and its tributaries by industrial wastes. February 20, 1914.

Hammon, Harry B., Sanitary Chemist. Directed to proceed to Washington, D. C., for instructions in connection with sanitary disposal of industrial wastes. February 10, 1914.

BOARD CONVENED.

Board of medical officers established at San Francisco, Cal., for the re-examining of detained aliens. Detail for the board: Surgeon W. C. Billings, chairman; Surgeon M. W. Clover, member; Assistant Surgeon L. W. Jenkins, recorder. February 19, 1914.

Banks, C. E., Senior Surgeon. Leave of absence for 4 days from February 20, 1914, amended to read "7 days' leave of absence from February 20, 1914." February 19, 1914.

von Ezdorf, R. H., Surgeon. Directed to report at the Bureau, Washington, D. C., March 4, 1914, for conference relative to malaria investigations. March 2, 1914.

Lumsden, L. L., Surgeon. Detailed, at the request of the Maryland Medical and Chirurgical Faculty, to deliver an address before that society, at Baltimore, Md., March 9, 1914, on "Public Health Education." March 2, 1914.

Robinson, D. E., Surgeon. Relieved from temporary duty in the Hygienic Laboratory and directed to proceed, via New York, N. Y., to Cincinnati, Ohio, for investigations of tu-

berculosis in relation to occupation and environment. February 25, 1914.

Corput, C. M., Surgeon. Granted 4 days' leave of absence from February 23, 1914, under paragraph 193, Service Regulations. February 22, 1914.

Thometz, H. M., Assistant Surgeon. Relieved from duty at the Marine Hospital, San Francisco, Cal., and directed to proceed to the San Francisco quarantine station, Angel Island, Cal., and report to the medical officer in charge for duty and assignment to quarters. February 28, 1914.

Ruoff, J. S., Assistant Surgeon. Granted 30 days' leave of absence from January 24, 1914, on account of sickness. March 3, 1914.

Wayson, Newton E., Assistant Surgeon. Directed to proceed to San Francisco, Cal., and report to Surgeon John D. Long for duty in plague suppressive measures. February 28, 1914.

Galloway, Thomas C., Jr., Assistant Surgeon. Directed to proceed to San Francisco, Cal., and report to the medical officer in charge of the Marine Hospital, for duty and assignment to quarters. February 28, 1914.

Waller, Clifford E., Assistant Surgeon. Directed to proceed to Baltimore, Md., and report to the medical officer in charge of the Marine Hospital for duty and assignment to quarters. February 28, 1914.

Sutton, Don C., Assistant Surgeon. Directed to proceed to Chicago, Ill., and report to the medical officer in charge of the Marine Hospital for duty and assignment to quarters. February 28, 1914.

Faget, Frank M., Assistant Surgeon. Directed to report to the medical officer in charge of the New Orleans quarantine station for duty and assignment to quarters. February 28, 1914.

Lison, John H., Assistant Surgeon. Directed to proceed to Detroit, Mich., and report to the medical officer in charge of the Marine Hospital for duty. February 28, 1914.

Akin, Charles V., Assistant Surgeon. Directed to proceed to New Orleans, La., and report to the medical officer in charge of the Marine Hospital for duty and assignment to quarters. February 28, 1914.

Miller, Knox E., Assistant Surgeon. Directed to proceed to Stapleton, N. Y., and report to the medical officer in charge of the Marine Hospital for duty and assignment to quarters. February 28, 1914.

Wilson, Joseph C., Assistant Surgeon. Directed to report to the Chief Medical Officer, Immigration Station, Ellis Island, N. Y., for duty. February 28, 1914.

Staton, L. W., Acting Assistant Surgeon. Directed to proceed to West Point, Va., for investigation of case of smallpox on schooner "Lizzie Hall." February 27, 1914.

APPOINTMENTS.

Doctors Newton E. Wayson, Thomas C. Galloway, Jr., Clifford E. Waller, Don C. Sutton, Frank M. Faget, John H. Lison, Charles V. Akin, Knox E. Miller and Joseph G. Wilson commissioned Assistant Surgeons in the United States Public Health Service. February 24, 1914.

BOARD CONVENED.

Board of medical officers convened to meet at the Marine Hospital, Mobile, Ala., for the physical examination of First Lieutenant of Engineers C. S. Root, U. S. R. C. S. Detail for the board: Surgeon R. H. von Ezdorf, chairman; Assistant Surgeon R. C. Derivaux, recorder.

Mathewson, H. S., Surgeon. Directed to proceed to Ellis Island, N. Y., to study methods there used in the examination of aliens suspected of mental defects. March 7, 1914.

Spratt, R. D., Passed Assistant Surgeon. Relieved from duty at Ellis Island, N. Y., and directed to proceed to Gloucester City, N. J., reporting to Surgeon Fairfax Irwin for duty in the examination of arriving aliens. March 7, 1914.

Frost, W. H., Passed Assistant Surgeon. Detailed, at the request of the Director of the Illinois Water Supply Association, to attend a meeting of that Association, to be held at Urbana, Ill., March 9-11, 1914. March 3, 1914.

de Valin, Hugh, Passed Assistant Surgeon. Upon completion of duties as Recorder of Board of Examiners, directed to make a study of the question of the pollution of railway tracks between Washington, D. C., and Baltimore, Md., March 3, 1914.

Guthrie, M. C., Passed Assistant Surgeon. Relieved from duty in the examination of arriving aliens at Gloucester City, N. J., and directed to proceed to the Canal Zone and report to the Governor of the Panama Canal, relieving Surgeon J. C. Perry, for duty in connection with the maritime quarantine of the Canal. March 7, 1914.

Herring, R. A., Passed Assistant Surgeon.

Relieved from duty at Ellis Island, N. Y., and directed to proceed, by way of Washington, D. C., to Spartanburg, S. C., for duty, under Surgeon Joseph Goldberger, in connection with pellagra investigations. March 3, 1914.

Ridlon, J. R., Passed Assistant Surgeon. Relieved from duty at Philadelphia, Pa., and directed to proceed, by way of Washington, D. C., to Spartanburg, S. C., for duty, under Surgeon Joseph Goldberger, in connection with pellagra investigations. March 3, 1914.

Gillespie, J. M., Assistant Surgeon. Relieved from duty at the Hygienic Laboratory, and directed to proceed to Ellis Island, N. Y., and report to the Chief Medical Officer for duty. March 7, 1914.

Thometz, H. M., Assistant Surgeon. Granted 6 days' leave of absence from January 26-31, 1914, on account of sickness. March 10, 1914.

Townsend, J. G., Assistant Surgeon. Relieved from duty at the Marine Hospital, Baltimore, Md., and directed to proceed to Ellis Island, N. Y., and report to the Chief Medical Officer for duty. March 3, 1914.

Hoskins, John X., Sanitary Engineer. Directed to proceed, as instructed by the officer in charge of the Ohio River investigations, to various points for laboratory studies and sanitary surveys of the Ohio River watershed. March 5, 1914.

Lowe, Dan., Epidemiologist. Directed to proceed to Washington, D. C., for conference and instructions, and thence to such places as directed by the medical officer in charge of the work, for duty in connection with the epidemiological survey of typhoid fever. March 7, 1914.

BOARD CONVENED.

Board of commissioned medical officers convened to meet at the Bureau, Monday, March 9, 1914, for the examination of candidates to determine their fitness for appointment as Assistant Surgeons in this Service. Detail for the board: Assistant Surgeon General W. G. Stimpson, chairman; Surgeon C. H. Lavinder, member; Passed Assistant Surgeon Hugh de Valin, recorder. March 3, 1914.

Banks, C. E., Senior Surgeon. Granted 7 days' leave of absence from March 6, 1914. March 5, 1914.

Guiteras, G. M., Surgeon. Leave of absence for 1 month amended to read "4 days'

leave of absence from February 21, 1914." March 14, 1914.

Wertenbaker, C. P., Surgeon. Granted 10 days' leave of absence from March 10, 1914. March 13, 1914.

Brown, B. W., Surgeon. Relieved from duty at Yokohama, Japan, and directed to proceed to San Francisco, Cal., and report arrival to the Bureau and there await orders. March 11, 1914.

Lavinder, C. H., Surgeon. Relieved from temporary duty at the Hygienic Laboratory and directed to rejoin station at the Marine Hospital, Savannah, Ga. March 11, 1914.

Lumsden, L. L., Surgeon. Directed, at the request of the Health Department of Cumberland, Md., to proceed to that city for the purpose of addressing a public meeting on March 13, 1914, on the subject of means necessary to prevent typhoid fever. March 13, 1914. Granted 2 days' leave of absence, on account of sickness, from March 2, 1914. March 11, 1914.

White, M. J., Surgeon. On request of the Industrial Commission of Indiana, directed to proceed to Indianapolis and other points within that State, to co-operate with said Commission and representatives of the Federal Bureau of Labor Statistics on investigations of sanitary conditions of factories and workshops and studies of physical status of workers. March 10, 1914.

Fricks, L. D., Surgeon. Directed to proceed to Victor, Mont., for the purpose of carrying on operations for the prevention of the interstate spread of Rocky Mountain spotted fever. March 17, 1914.

Moore, Dunlop, Surgeon. Granted 1 day's leave of absence, March 2, 1914, on account of sickness. March 10, 1914.

Gwynn, M. K., Surgeon. Granted 2 days' leave of absence, March 2-3, 1914, on account of sickness. March 11, 1914.

Schereschewsky, J. W., Surgeon. Directed to proceed to New York, N. Y., for the purpose of attending the postponed meeting of the Hygiene Committee of the National Council for Industrial Safety, March 12, 1914. March 10, 1914.

Boggess, J. S., Surgeon. Relieved from duty at the Mobile quarantine station and directed to proceed to Yokohama, Japan, for duty in the office of the American Consul-General. March 11, 1914.

Wilson, R. L., Surgeon. Granted 7 days'

additional leave from March 24, 1914. March 14, 1914.

Parker, H. B., Passed Assistant Surgeon. Relieved from duty at Ellis Island, N. Y., and directed to proceed to Guayaquil, Ecuador, for duty in the office of the American Consul-General. March 11, 1914. Granted 1 month's leave of absence from March 10, 1914. March 11, 1914.

Collins, G. L., Passed Assistant Surgeon. Relieved from duty in connection with the trachoma clinic at Hindman, Ky., and directed to proceed to Boston, Mass., and report to the medical officer in charge of the Marine Hospital for duty and assignment to quarters. March 14, 1914.

Turnipseed, D. C., Assistant Surgeon. Relieved from duty in Quarantine Service of the Philippine Islands and directed to proceed to San Francisco, Cal., and report arrival to Bureau and there await orders. March 11, 1914.

Kearny, R. A., Assistant Surgeon. Granted 20 days' leave of absence from April 20, 1914. March 13, 1914.

Watkins, J. A., Assistant Surgeon. Granted 7 days' leave of absence upon completion of course of instruction at Hygienic Laboratory. March 13, 1914.

Laughlin, J. B., Assistant Surgeon. Relieved from duty at the Gulf quarantine station, and directed to proceed to the Mobile quarantine station and assume charge, relieving Surgeon J. S. Boggess. May 11, 1914.

Bolten, Joseph, Assistant Surgeon. Relieved from duty at Detroit, Mich., and directed to proceed to Chicago, Ill., and report to the medical officer in charge of the Marine

Hospital for duty and assignment to quarters. March 11, 1914.

Voegtlin, Carl, Professor of Pharmacy. Directed to proceed to Spartanburg, S. C., for conference with Passed Assistant Surgeon R. A. Herring to determine the availability of that location for special studies of metabolism in relation to the causation of pellagra. March 13, 1914.

Wickliffe, T. F., Acting Assistant Surgeon. Directed to proceed from Hyden to Jackson, Ky., to take charge of the trachoma work at the later place. March 12, 1914.

Hommon, Harry B., Sanitary Chemist. Directed to proceed to Baltimore and Luray, Md., and other places on the Potomac River watershed to make special field studies of sanitary wastes. March 17, 1914.

Stearns, W. L., Pharmacist. Reassigned to duty at the Marine Hospital, Stapleton, N. Y., effective March 24, 1914. March 13, 1914.

Smith, L. G., Pharmacist. Directed to proceed to Blackbeard's Island, to arrange for the transfer of property to the Savannah quarantine station, to be utilized in pellagra investigations. March 16, 1914.

BOARD CONVENED.

Board of medical officers convened to meet at the Bureau, March 18, 1914, for the purpose of revising the Telegraphic Cipher Code of the Service. Detail for the board: Assistant Surgeon General L. E. Cofer, chairman; Assistant Surgeon General W. C. Rucker, member; Passed Assistant Surgeon Hugh de Valin, recorder. March 17, 1914...

Official:

RUPERT BLUE,
Surgeon General.

THE NUMBER OF TECHNICAL CHEMISTS IN GERMANY.

According to the annual statistics published by the Society of German Chemists in 339 German chemical works 268 were either proprietors or directors, while in all there were employed 2,467 university-trained chemists and 384 technical chemists, i. e., without a university education. There are at present twenty firms which each employ over twenty chemists; these employ altogether, in addition in forty-five independent chemists, 1,477 chemists, and 154 technical chemists; that is to say, that over half of all the chemists included in these statistics are in the employ of these twenty large firms. During the year 1912-13 winter term there were 3,082 chemical students working in the laboratories of the German universities, of whom 2,649 were Germans.—*The Chemist and Druggist* (London).

PUSHING PHOTOGRAPHIC SUPPLIES.

The business builder has one of his finest opportunities here. Most druggists realize this. In all the smaller towns you will find druggists carrying full lines of cameras and supplies and doing a roaring business. Almost every human being gets the camera craze at some stage, and this tendency is certainly good for business. It makes cameras almost as staple as shoes. Of course, not all of us can gratify our little desires, but most of us can. The business in photographic supplies is naturally very large. It may be augmented by encouraging camera clubs, or organizing the same where none exists. Every town should have a camera club. It gives the young people the right kind of recreation and will be found helpful to the standard of citizenship in that town. Towns where the young men loaf on street corners, making smart remarks and exchanging doubtful stories, are not good towns for turning boys into high-minded men. A camera club has a social side and helps out wonderfully in places where there is little offering in the way of high-class entertainment. Some dealers offer cash prizes for photographs, and some very interesting contests have been worked up along these lines.

In one contest of this kind, cash prizes were offered as follows: A first prize of \$25 for the best photograph posed with living figures, second prize of \$15 for the best photograph of a local building inside the town limits, third prize of \$10 for the best photograph of a residence within the county but outside the town limits, and fourth prize of \$10 for the best photograph of any farm scene taken inside the county. The decisions were rendered by a committee elected by the camera club with the town mayor as chairman. The entire town and county participated more or less in this contest, the local paper gave it some good advertising, and altogether a great deal of interest was aroused. An exhibition of the photographs is a good thing, and this may be held in the rooms of the camera club, with the general public invited.

It might be practicable for all dealers in photographic supplies in a certain town to combine and offer prizes open to all amateurs. These enterprises boom business, enliven the town, and are good things all around. You can always get hearty co-operation from the local press and plenty of free advertising. When a town is dragging along in a rut, it always helps when somebody starts a proposition of this kind. A friendly rivalry wakes the people up, the surrounding country becomes interested, trade is brought into town, and the town gets some good advertising. Such are the things that boards of trade in all towns are working for. The whole population benefits. Money put into circulation helps everybody.

Annual, or semi-annual exhibitions are good things. Many camera clubs have given these, in the larger cities as well as in small towns. The druggist in the large city can handle cameras and photographic supplies to advantage. He can't get all this trade, as some of it will go down town to the regular supply houses. But druggists should bear in mind that a big city is only a collection of small towns. If you are out on the edge of the city you are still in the center of your own settlement. Many of your customers will buy all their supplies from you. Occasionally they go shopping down town, but by going after it, you can get the bulk of their business.—W. S. Adkins in *The National Druggist*.

A QUESTION OF PROFESSIONAL ETHICS.

"I PRACTICE in a small town and do a prescription business. I write, say a prescription for a cough. A neighbor or friend has a cough, they get the number off the bottle and take it to the druggist who fills it, knowing that the mixture was not prescribed for the person for whom he is now filling it. I told him [the druggist] not to do so. Has he a legal right to do this? This has happened so many times that I am ordering a small stock of drugs to dispense my most common remedies."

The above, being purely an *ex parte* statement of facts, does not present the qualifying or extenuating circumstances which the druggist might be able to set forth if given his day in court, and we shall therefore express no opinion as to his guilt or innocence of the offense as charged.

While there have been a few cases in the lower courts where the ownership of prescriptions has been under consideration, the writer has not been able to discover any authoritative ruling by a court of last resort upon the rights of physicians to control the fate of their prescriptions after they have been delivered to the patient.

In the absence of any legal authority one guess is about as good as another. A court might rule that the pharmacist was merely the custodian of the piece of paper upon which the recipe was written, and not the owner either of the paper or the recipe; or it might take the ground that the physician passed over all of his property rights to the patient and that the latter alone had the right to control the number of times the prescription should be refilled. To the writer it would seem to be a reasonable doctrine to regard the prescription as an order for a specific transaction, like a check on a bank, and that when the medicine has been compounded and delivered the virtue of the order is exhausted, except as a record of the transaction.

The question is of such importance that an authoritative ruling is much to be desired, and it would be a work of merit for some pharmaceutical society to join with some medical society in a friendly suit to determine the matter. The value of the decision would, of course, depend largely upon the manner in which the case was framed and the distinctness with which its several issues were set forth. One well considered decision by a state appellate court would no doubt be generally accepted as settling the subject until set aside by positive legislative enactments.

It is because a proper spirit of professional comity has so generally controlled the relations of pharmacists and physicians that these have been permitted to go unregulated by statute. It is only when some exceptional case arises, like the present one, that they are brought into question.

The legal questions involved are, however, the least important part of the query.

By common consent it is agreed that the man who is merely "law-honest," that is, who recognizes only such obligations as the law imposes in set terms and definitions, is neither a good neighbor nor a desirable citizen. And it is equally true that the druggist who measures his obligations to the medical profession and the public solely by the positive declarations of the statutes is neither a good citizen nor a desirable member of the pharmaceutical fraternity.

Upon what ethical or professional ground can a pharmacist justify his act in refilling a prescription, when such repetition has been expressly forbidden by the prescriber?

It is so common for physicians to give a patient verbal directions to have a prescription refilled that we believe pharmacists are justified in refilling them when they have no notice of any contrary desire on the part of the prescriber. But when the physician has plainly expressed the wish that a prescription shall not be refilled, then that wish must in every case be respected by the custodian of the prescription. This, it is believed, represents both the theory and the practice of the great majority of pharmacists. Any other rule would be a menace to the public health and direct invitation to reprisals by the medical profession.

That all druggists do not rigidly observe the rule of comity must be admitted with regret, but so far as the writer's observation extends the men of this class are comparatively few in number and far between. The majority of pharmacists are far too anxious to convince the prescribing physician of their trustworthiness to take any undue liberties in the way of refilling or in other respects.

In fact it would be difficult to explain or define the motives that could influence a pharmacist to deliberately disregard the prescriber's wishes concerning refills. Certainly it cannot be self-interest, since properly enlightened self-interest would dictate just the opposite course of conduct. When such things do occur, they can be due only to that mixture of general perversity, stupidity and petty meanness which is colloquially expressed as "pure cussedness."

If only the druggists who did such things were concerned, their punishment might safely be left to the physicians whose confidence they have betrayed, but unfortunately as things exist in this vale of tears, the innocent too often must suffer with the guilty, and all of the members of a class for the faults of a few.

Such actions make a mockery and a joke of the propaganda for better pro-

fessional comity. One deliberate disregard of a physician's request not to refill a prescription can do more harm than a dozen get-together meetings can remedy. To invite physicians to a propaganda dinner and meeting, and then conduct one's business in violation of professional ethics amounts to chucking them under the chin with one hand and clubbing them over the head with the other.

If ever thoroughly harmonious relations are to prevail between medicine and pharmacy they must come mainly through the growth of a good understanding and of a spirit of mutual helpfulness between them, and whatever will help in promoting this better understanding or make either profession more useful to the other is a desirable instrument of the propaganda.

If the pharmacist desires the confidence of the physician he must observe that confidence when extended; if he desires the patronage of the physician, either direct or through the medium of written prescriptions, he can obtain it by serving the physician better than any one else can serve him in the same line. Whenever this kind of service has been rendered it has resulted in the professional and financial prosperity of the pharmacist.

The extent to which the law can go in promoting these good relations between the two professions is limited. It cannot properly interfere merely to protect the business of the physician against the pharmacist, nor can it compel the physician to write prescriptions simply because the pharmacist needs the money. It can take cognizance of such things only so far as they are directly connected with the general public welfare.

For example, a statute might very properly prohibit the refilling of a prescription without the express permission of the prescriber, but this prohibition would not be for the purpose of giving the physician a monopoly, but for the reason that in many cases the continued use of a given medicine or its promiscuous passing around the community would be dangerous to the public health. Such a statute would simply be converting what is generally recognized as a professional obligation into a legal obligation which all would be compelled to observe.

Again, the law might properly prescribe that physicians who desired to dispense their own medicines should demonstrate their ability to do such dispensing before an impartial and unprejudiced board or commission, because the compounding and dispensing of medicines and their application to the treatment of disease are separate arts, and a man may be well qualified to practice one and not the other.

The physician is either qualified to dispense or he is not. If qualified, it should be easy to demonstrate that fact before an impartial commission; if he is not qualified, then the more reason why he should not be permitted to dispense. Here, however, we should not lose sight of the fact that there are different grades of compounding and dispensing. If the physician prefers to use tablets, serums, or other agents the preparation of which is completed before they reach his hands, it would be difficult to convince the average legislature that he should not be permitted to do so, unless it can be shown that the use of such medicaments will be productive of injury to the public.

Again the law might very properly require that the stock of drugs and medicines kept by the physician should meet the same requirements of purity and strength as are enforced with regard to the pharmacist.

Probably no one would claim that the physician ever deliberately purchases inferior or deteriorated drugs. When he does purchase them it is because he has been careless in selecting the source of supply, or because he has permitted some smart salesman to convince him that his cheap drugs are the equal of the higher priced ones of the well known manufacturer. Before the enactment of food and drugs laws, pharmacists sometimes "took a chance" on such propositions. If they do so now the chances are that they will be sorry.

There is no reason why the physician cannot have the best of everything if he is willing to pay the price and deals only with manufacturers or retailers of established reliability, and there is also no reason why the incautious ones among them should not be discouraged from taking chances, the same as pharmacists have been discouraged.

The only sound and permanent foundation for the satisfactory adjustment of the relations between pharmacy and medicine is the creation of mutual respect and mutual confidence between the members of the two professions. All that the statute law can do is to act as a palliative or as a corrective of the grosser abuses. Laws should not be specially constructed by physicians to curb pharmacists, nor by pharmacists to curb physicians. Measures designed to define the limits between medicine and pharmacy should be draughted by joint committees chosen from both—committees composed of men who are broad enough to realize that such a boundary line cannot be drawn as sharply as the lines on an architect's blue print, and who are ready both to give and to take in the compromise of disputed points.

J. H. BEAL.

UNITY OF EFFORT.

WE live in an age of activity. Everywhere there is the bustling movement of mankind, engaged in the desire for more business, for changed conditions in almost every walk of life,—in ethics, in politics, in social conditions and in every possible outlet for superabundant vitality, until one is almost tempted to ask at times, "*Cui Bono?*" Is it for betterment that the whole world is seething and fretting and fuming for change, some of these changes being those upon which the staid and sober citizen looks with askant eye?

For change does not always mean improvement and all activity is not for the best, all speed does not always win the race. We have Biblical authority for the statement that, "The race is not always to the swift," nor is excessive activity even in trade matters always for the best. In these, as in all other things of life, moderation accomplishes most in the end. It is of little service to the betterment of our profession to seek with confused effort to accomplish real and valuable things. Attempts looking toward reform should be made with calm, deliberate thought by which only the best results can be achieved. The cause of much confusion to-day is the lack of correlation between the minor organizations of the trade and the two great national bodies. Local organizations have a most useful place but would they not be more useful if they were organized as co-ordinate parts of a greater whole, and if all these bodies were striving for a common good? Con-

sider the strength which would be exerted by these various organizations if they were united in support of a common purpose, such as a model liquor law or a poison law such as might be framed by the able men of the national associations. See what a bulwark of defense would be a model law proposed by these men of national reputation and supported zealously all along the line by the united organizations of the trade. Now we fritter away our efforts in small-arm firing, but united we would wage our battle with the mighty projectiles of modern artillery.

See the good which has been accomplished through the unity of effort of the National Drug Trade Conference, and this same good would flow from any effort backed by the united trade in a like way. We would then have no such freak-legislation as cumber the statute books of many of our states to the great vexation of the members of the profession, but there would arise a sane and safe legislation which would result in good for all.

Why should not all these local organizations be parts of a greater whole? Be auxiliary to the A. Ph. A. and the N. A. R. D. and closely identified with them? Each of these bodies having its A. Ph. A. section and its N. A. R. D. section and each attracting to their meetings those interested in the special work of its sections? These two great national bodies are nobly doing their work in the advancement of pharmacy. But beneath these organizations there is confusion in which there is no unity of effort, from which lack, there results no wise progress. He who reads the reports of the various state associations, even with a careless eye, will hardly fail to observe that some give all their thought to the development of but one side of our profession, while others devote themselves almost entirely to the other side, few of them working for the harmonious development of the whole body, for that development which makes for the all-around good of the profession. Why should these associations so neglect the other side and seek for but the development of the one side? To be a pharmacist in these days requires a development along both of these lines. One must be commercial as well as scientific to be an all-around pharmacist. The pendulum must swing in sure and even beat for the clock to mark true and accurate time; if "out of beat" it may run, but without accuracy. So should we all endeavor to have the pendulum of pharmacy swing true for the proper development of the profession as a whole; for the development of its science and the development of its commerce and these can go hand-in-hand for the making of a nobler Pharmacy, a Pharmacy of the highest ideals and purpose.

ERNEST C. MARSHALL.

DETROIT, THE CONVENTION CITY.

The Detroit meeting of the A. Ph. A. in August promises to be in many respects the most delightful in the history of that venerable association.

It is worth a trip across the continent any time just to see Detroit, for beyond all question it is the most beautiful city in America. New York is awe-inspiring—and is sometimes said to be awful—Chicago is wonderful, Philadelphia, Boston and Washington are rich in historic associations, but in Detroit nature has done everything she could and Detroit folks have done the rest.

Most people do not realize that in the past fifteen years the population has practically doubled—that Detroit has changed from an overgrown town to a big city. The visitors here next August will see not only the greatest drug houses in the world, they will also see the greatest automobile, adding machine, varnish, stove and other manufacturing plants.

They will see the city whose building activities every year regularly outstrip every other city in America except New York, Chicago and one or two other of the most populous centers.

The local entertainment committee has almost completed its plans to make every hour enjoyable to the visiting A. Ph. A. members, but maintains a profound secrecy as to details. The complete program will be announced soon.

However, no one who has ever attended a big Detroit convention entertains any doubt about the recreational features of this meeting. The finest pleasure boats in the world are here and the variety of river and lake trips offered is limited only by the amount of time one has to spend that way.

And for those who would like a taste of motoring, the wide shaded streets and boulevards, the beautiful lake shore drive through Grosse Pointe, the millionaires' suburb, and the wonderful concrete roads extending in every direction through Wayne county will furnish a temptation too great to be resisted.

An easy two hours' run to the west by motor car brings one to Ann Arbor. Certainly it would be a mistake to leave Detroit without going there to see the great University of Michigan, whose school of pharmacy with its spacious and perfectly equipped laboratories contributes so much to the advance of pharmaceutical science.

This A. Ph. A. meeting offers the overworked druggist a rare opportunity for a week of improvement and recreation that should not be overlooked. Come along. Even if you are not a member of the Association, come anyway—you will be welcome. The Association wants you. Detroit wants you. And it will be good for what ails you.

Papers Presented at the Sixty-First Annual Convention

"LLOYD'S REAGENT"*—PRELIMINARY ANNOUNCEMENT.

JOHN URI LLOYD, PHAR. M.

The writer proposes to contribute to the 1914 meeting of The American Pharmaceutical Association (probably to the *Historical Section*), a paper concerning a newly discovered alkaloidal reagent, known to a few persons only, at this date, under the name "Lloyd's Reagent," the reagent itself being a form of Hydrous Aluminum Silicate. His paper will be devoted, mainly, to its discovery and application as an alkaloidal reagent, together with such connected features as appeal as being of interest, historically and otherwise. This delay of a year is necessary, not alone on the writer's account, but because a few chemists, microscopists and physicians have already instituted experimental processes in connection with special phases of the subject, and to their researches credit should be awarded.

The alkaloidal opportunities of this newly discovered reagent are shown by the specimens, herewith exhibited, of *Gelseminine* (ether soluble), natural alkaloid, and natural Nicotine. The first of these, a fixed alkaloid, is considered rare, and is generally accepted as difficult to obtain in quantity; the second is volatile, and prone, under most processes, to manipulative changes. To neither of these has any heat whatever, or any decolorizing agent been applied, the Nicotine being made without distillation.

With this preliminary note calling brief attention to the subject, the writer voices his hope that when comes the next meeting of this Association, he may be in a position to present a fairly comprehensive, as well as more satisfactory communication than is possible at this date.

REMARKS ON LLOYD'S REAGENT.

Remarks by J. U. Lloyd, on being asked to read the paper of Dr. Gordin and Mr. Kaplan on the Qualities of Lloyd's Reagent¹:

I am naturally more than interested in what Dr. Gordin and Mr. Kaplan may say in this communication concerning this alkaloidal reagent, that is probably a new one to most members of our Society. I cannot refrain from expressing my thanks to both the authors of the paper and to the Society, in that I am privileged to read this paper, for I feel that I am highly honored in being thus selected. It

* See Dr. Sigmund Waldbott's announcement in the *Journal of the American Chemical Society*, June, 1913, and Dr. M. I. Wilbert's contribution to the Pennsylvania Pharmaceutical Association, reported in *The American Druggist*, July, 1913.

¹ Prof. Lloyd's remarks during the reading of this paper, as various phases of the subject were presented, are herein included.

would please me much were Dr. Gordin present with us, because I feel that the problems presented might lead to advantageous discussions, were he here. His absence, however, renders it permissible, and perhaps necessary, that I make some preliminary remarks concerning the reagent mentioned in the paper that I hold in my hand, as well as take the liberty of introducing, discreetly, a few comments as I proceed. It is with more than a little reluctance that even under these circumstances, I venture to intrude a few personal remarks, in directions that appeal to me as requiring special mention, but in it all I feel the authors will acquiesce.

The reagent to which Dr. Gordin refers in this paper, and which he calls simply, "Lloyd's Reagent for Alkaloids," is a form of hydrous aluminum silicate that I obtain from clay and earths. The most prolific source of supply that I have as yet discovered, is the well known "fuller's earth," which indeed carries in its crude form, most marked alkaloidal qualities. My experiences lead to the inference that the alkaloidal qualities of the material are not, however, due to the inorganic side of the compound, other than when combined with water. In fact, if the water be totally expelled from the hydrous aluminum silicate, all alkaloidal attraction disappears.

Another feature of the reagent that in a preliminary manner I need mention properly before reading this paper, is the fact that the *physical* form of the compound has much to do with its alkaloidal energy. In making and extracting this compound from the forms of clay that I have investigated, I have found it desirable, as nearly as possible, to bring the abstracted and hydrated material into a colloidal condition, in which form, before being dried, it has an intense affinity for alkaloids and alkaloidal salts. Indeed, the nearly transparent, practically colloidal form, is instantaneous in its action, there being scarcely an element of time between the absolute separation of any alkaloid yet investigated, whether in the form of salts or otherwise, from solution in water or acidulated water.

It may not be out of place for me to state that the contents of no two clays or specimens of fuller's earth seem to have the same *structural* qualities and affinities. The variations of the material obtained from different forms of fuller's earth are much greater than would be supposed to exist. The common blue clay of our hills and rivers, likewise carries qualities exceedingly variable.

Nor may it be out of place for me to state in connection with this paper of Dr. Gordin and Mr. Kaplan, that I have been bitterly disappointed in that clays that I, theoretically, supposed would be prolific in the yielding of the purest and strongest alkaloidal "attractives," but which proved to be the very reverse. Thus, the pure white aluminum silicate obtained from the Rookwood Pottery in Cincinnati, so celebrated for its beautiful wares, was found to be almost passive, when it came to the alkaloidal test.

It pleases me much to note in this paper, the comparison between charcoal and hydrate of aluminum, with my reagent. It shows that the length of time required for charcoal attraction, and the absence of alkaloidal qualities as concerns the hydrate of aluminum, agree with my experiences therewith. And also that the hydrated aluminum silicate (Lloyd's Reagent), for many bitters and different substances of drugs, has little, if any, attraction.

In making these remarks, which I feel due both to the writers of the paper and

to myself, as well as a privilege that I enjoy, I would like to add that Dr. Gordin uses the word "adsorption," as explaining the alkaloidal phenomena. Possibly he has accepted the word as employed by me in corresponding with him, and possibly he has made a scientific investigation to prove that it is altogether adsorption, or contact action, and not a chemical combination, after the manner of the usual alkaloidal reagents. Be this as it may, I wish to assume the responsibility of error of application, in case the doctor has used the word as taken from myself, and has thus been lead into accepting that view of the subject without personal investigation. Should it be shown by future experimentation that there is a chemical reaction other than adsorption, he, if the fault be mine, should be absolved from all responsibility therein.

Let me again express my deep regret that Dr. Gordin and Mr. Kaplin are not here to-day, to make a personal presentation of this paper to the Society, and let me again express my personal appreciation of the honor that has been extended me by the personal request that I read to the Society this contribution.

NOTE ON COMPARATIVE ADSORPTION OF DIFFERENT SUBSTANCES BY LLOYD'S REAGENT, ANIMAL CHARCOAL AND ALUMINUM HYDROXIDE.

H. M. GORDIN AND JAY KAPLAN.

Prof. John Uri Lloyd, in a private communication, informed me that he has discovered a reagent which quickly and completely adsorbs alkaloids from the aqueous solutions of their salts. The reagent is a natural aluminum silicate treated by a special method which he has patented in this country and will be patented abroad. Providing me with a liberal supply of the reagent, he asked me to verify his statement about the efficiency of the reagent for the complete removal of alkaloids, and gave me permission to institute upon the reagent any other set of experiments I might consider advisable. Since animal charcoal and freshly precipitated aluminum hydroxide are very much used for the removal of various substances from solution, I set up a series of experiments upon these two adsorbents along with Lloyd's reagent.

The results of my experiments, tabulated in the tables at the end of this note, may be summarized as follows:

1. The reagent resembles animal charcoal in possessing the power of adsorbing alkaloids, glucosides, bitter principles and coloring matter. While in the scope of adsorbable substances charcoal most probably excels Lloyd's reagent, in velocity of adsorption of alkaloids, the reagent by far surpasses charcoal. The complete removal of alkaloids by means of charcoal usually requires digestion with continuous shaking for several hours, while the adsorption by Lloyd's reagent is complete within a few minutes.

2. The removal of alkaloids by either the reagent or charcoal is not influenced by the presence of free acid in the solution. Even alkaloids which in the free

condition are soluble in water, such as colchicine and caffeine, can be completely adsorbed either by charcoal or Lloyd's reagent.

3. Aluminum hydroxide, so effective in the removal of acid dyes with which it forms lakes, has very little adsorptive power for alkaloids, glucosides, and bitter principles.

4. The amount of reagent or purified animal charcoal required for the complete removal of alkaloids differs with the nature of the latter, and in the case of charcoal the removal is not complete unless the digestion and shaking of the mixture lasts a certain length of time.

5. Sodium chloride is not adsorbed by Lloyd's reagent.

6. Both the reagent and charcoal adsorb acids and alkalies.

The experiments on alkaloids were carried out as follows: Solutions of alkaloidal salts or of alkaloids in acidified water were shaken with such quantities of reagent or purified animal charcoal and for such periods of time as were found by preliminary experiments to be in all cases sufficient for the complete removal of the alkaloids. The solutions were then filtered, and the acid or acidified filtrates tested with Mayer's and Wagner's reagents.

Berberine was also tested for by picric acid which is extremely delicate for this alkaloid, and for isocalycanthine the very sensitive test with gold chloride and sodium carbonate was used in addition to Mayer's and Wagner's reagents.

In working with aluminum hydroxide a comparatively large amount of aluminum sulphate was added to solutions of alkaloidal salts, and the liquids made strongly alkaline with ammonia. After shaking for some time, the liquids were filtered, and the filtrates tested as above.

In testing for the adsorption of salicin, amygdalin and aloin, the filtrates were examined by evaporating aliquot portions to dryness and weighing the residues.

In the experiments with sodium chloride the amount of the latter in the filtrate was determined by titration with standard silver nitrate.

In the experiments on the adsorption of acid and alkali the amounts of these in aliquot portions of the filtrates were determined by titration.

Another series of experiments were made in order to determine whether it would be possible to make use of either charcoal or Lloyd's reagent for the complete removal of an alkaloidal salt in presence of free acid, together with a definite amount of this acid. If this were possible, we would have here a convenient method for the quantitative determination of alkaloids. All we would have to do would be to dissolve the given alkaloid in an excess of standard acid, remove the alkaloidal salt so produced together with a definite amount of the free acid by means of the adsorbent, and then titrate the excess of acid remaining in solution. Experiments showed, however, that both Lloyd's reagent and charcoal adsorb such amounts of free acids as are entirely independent of the amount of alkaloid taken. The acid adsorbed varies with the concentration of acid, alkaloid and amount of adsorbent used.

Attempts to make the method workable by standardizing the acids against known amounts of the alkaloids failed to give concordant results. Hence the expectations in this respect were not realized.

Table IV at the end of this article is taken from Lloyd's private communication.

NORTHWESTERN UNIVERSITY SCHOOL OF PHARMACY, Chicago, Ill., June 24, 1912.

TINCTURE OF CANTHARIDES—CONTINUED.

WILBUR L. SCOVILLE.

In 1910 I called the attention of this Association to the fact that the official Tincture of Cantharides is unwittingly misbranded, in that it does not and cannot properly represent the drug. Operating on four different samples of cantharides, by the official process, I found that 30%, 44%, 54% and 63% of the activity of the respective drugs used was represented in the tinctures. By using a menstruum of 10% Glacial Acetic Acid and 90% of alcohol, by volume, tinctures were prepared from three of these drugs which represented 81%, 87% and 91%, respectively of their activities.

This acid menstruum has been declared objectionable by some, though for what reasons I have thus far been unable to discover, since acetic acid is an excellent adjuvant to the action of cantharides.

Last year I presented a second paper on the subject in which the results of fifteen further attempts at making a representative tincture were shown. These experiments were made with menstrua composed of alcohol-acetone, alcohol-chloroform and alcohol-acetic ether, each being supplemented by the addition of 0.5 parts of acetic acid per 100 volumes, to free the cantharidin. The results showed an exhaustion of 26% to 46% by the usual percolation method, and 66% to 74% when the percolation was preceded by digestion at 40° to 50° C. The only conclusion from these experiments was that digestion is a very material aid to extraction, but even then the results were far from satisfactory. Furthermore the results were very puzzling, inasmuch as solvents had been used which were certainly capable of dissolving the cantharidin present, yet some had failed to extract any more than the best samples of a straight alcohol-menstruum. Also these results were less satisfactory than those obtained by direct percolation with a cold menstruum of alcohol-acetic acid.

In the present series, eighteen experiments have been made.

Since the beetles have shown a considerable indifference to alcoholic solvents under varying conditions, and even to mixtures of alcohol and chloroform, or alcohol-acetone and acetone-acetic ether, another line of attack was sought.

Reasoning humanly, a creature which could resist unlimited quantities of alcoholic liquids might succumb to hot water—a reasoning which had some support in the known effectiveness of boiling water in assaying the drug and its tincture, the following experiments were tried:

A—50 Gm. of drug, assaying 0.75% of cantharidin were digested with 25 cc. of diluted hydrochloric acid and 25 cc. of water for fifteen hours at a temperature of about 50° C., a reflux condenser being used. Then there were added 175 cc. of acetic ether and 275 cc. of alcohol, and the mixture macerated, with occasional shaking for two days, then filtered.

B—50 Gm. of the same drug were digested for fifteen hours with 25 cc. of diluted acid and 100 cc. of water, then 175 cc. of acetic ether and 200 cc. of alcohol were added and the mixture macerated two days before filtering.

C—50 Gm. of the same drug were digested with 25 cc. of diluted acid and

150 cc. of water for fifteen hours, then 175 cc. of acetic ether and 150 cc. of alcohol added, the mixture macerated during two days, then filtered.

Results—"A" Tincture (10% water) assayed 0.059 gm. per 100 cc.

"B" Tincture (20% water) assayed 0.066 gm. per 100 cc.

"C" Tincture (30% water) assayed 0.057 gm. per 100 cc.

These show an exhaustion of 78.6%, 88.8% and 76.0%, respectively, and indicate that the beetles yield in some degree to the hot water treatment, but that there are limits to which the menstruum can be diluted with water and still retain the cantharidin in solution.

The rest of the experiments were therefore conducted on this line, striving for conditions that would give a tincture which would fully represent the drug.

Experiment D tried 25% of acid-water and yielded 0.060 gm. cantharidin per 100 cc. or 80% exhaustion.

Experiments E, F and G were made to determine whether chloroform or acetic ether would give the best results in the menstruum.

These were made on a drug assaying 0.70% of cantharidin. E was made with 25% of acid-water and 35% of acetic ether (by volume) in the menstruum, and F with 25% of acid-water and 20% of chloroform. G was made with 25% acid-water and 20% acetic ether.

"E" Tincture assayed 0.054 gm. per 100 cc.=77.1% exhaustion.

"F" Tincture assayed 0.053 gm. per 100 cc.=76.0% exhaustion.

"G" Tincture assayed 0.057 gm. per 100 cc.=80.0% exhaustion.

This shows the perversity of the insects and leads to no conclusions.

Experiment H, made on the drug assaying 0.75% of cantharidin, used 35% of acid-water and 35% of acetic ether in the menstruum. Results=0.057 gm. per 100 cc. or 76% exhaustion—the same as C.

Experiment I, used the same drug and menstruum as C, but added the acetic ether to the hot aqueous mixture, shook until cold then added the alcohol and macerated the whole four days. Results=0.060 gm. per 100 cc. or 80% exhaustion—a trifle better than C.

Experiment J, used 25% water (including 50 cc. of acetic acid per 1000) and 20% of chloroform, and the same method as I—that is, the hot aqueous mixture was shaken with chloroform until the mixture became cold (about fifteen minutes) then the alcohol was added and the mixture macerated four days. Results=0.074 and 0.077 gm. per 100 cc., or 100%!

Victory at last! Here was a tincture which fully represented the drug used, and a drug of good grade, too. It had a brownish-green color, was a little darker than the present U. S. P. tincture and had a noticeable odor of acetic acid and of chloroform—though the latter was not as prominent as I had expected. It was brilliantly clear, and did not precipitate on standing several months—as ascertained afterward.

This was the first tincture in my experience which was known to fully represent the drug, and it only remained now to prove that the process would apply to various grades of drugs.

For the next experiment (K) an exceptionally rich drug was employed—one assaying 0.92% of cantharidin. The menstruum consisted of 25% water and

20% chloroform with acetic acid as the freeing agent and the chloroform added directly to the hot aqueous mixture and shaken until cold, as in experiment I. Result 0.064 gm. per 100 cc. or 70% exhaustion! This is tobogganing with a sharp start!

Experiment L.—Again 25% acid-water and 15% chloroform, and the mixture was digested three days after the chloroform had been well shaken as before. Result, 0.0745 gm. per 100 cc., or 81% exhaustion. This is better, but still considerably below 100%.

Experiment M.—Twenty-five percent acid-water and 20% chloroform treated as L. Result 0.075 gm. per 100 cc. or 81% exhaustion.

Experiment N.—Same as L but macerated in the cold instead of digesting the final mixture. Result 0.072 gm. per 100 cc. or 78% exhaustion.

Experiment O.—Twenty-five percent acid-water, 15% chloroform and macerate six days after the chloroform and alcohol were added. Result 0.068 gm. per 100 cc. or 74% exhaustion.

Experiment P.—The drug used on Experiments K to O, inclusive, was in a moderately coarse powder—about No. 40. Now some of this was ground to pass through a No. 80 sieve, then treated with 25% acid-water and 20% chloroform menstruum, the water digestion being continued for two days, then the mixture macerated one day with heat and two days without. Result 0.064 gm. per 100 cc. or 70% exhaustion.

Experiment Q.—Same as P but with shorter digestion and maceration—three days total. Result 0.057 gm. per 100 cc.=62% exhaustion.

Experiment R.—Twenty-five percent acid-water—which was digested at about 50° C. over night (15 hours) then on a steam-bath at 95° to 100° C. under a reflux condenser for six hours, then cooled to about 70° C., the chloroform 15% added and the mixture shaken until cold. Then alcohol (55%) added and the mixture macerated three days. Result: 0.056 gm. per 100 cc.=60% exhaustion.

Experiment S.—Twenty percent water, 35% acetic ether and 45% alcohol, digestion with water at 50° C. carried on 24 hours, then maceration with the rest two days longer. Result: .065 gm. per 100 cc.=70% exhaustion.

Conclusions: I have none. This is still a continued quest,—the conclusion to follow.

The cantharides fly seems to be like the proverbial flea—"when you put your finger on him he isn't there."

There is some encouragement in getting one tincture that fully represents the drug, but that is of little value unless the formula can be depended upon. In this case it worked on one drug, and not on another. And lest somebody questions whether the assay on this sample was reliable, let me say that three assays on this particular lot checked to 0.3% and in all the experiments at least two assays were made, the results checking closely. Probably long practice has enabled me to make assays of this drug and tincture with reasonable accuracy, though I do not expect very close results among different operators by the present known methods.

The present situation on the extraction of cantharides is as follows:

1. Alcohol alone fails to extract more than half to two-thirds of the cantharidin present.

2. Heat favors extraction, but has less effect in anhydrous than in hydrated menstrua.

3. The best menstruum thus far found is a mixture of one volume of glacial acetic acid with nine volumes of alcohol.

4. Mixtures of water, alcohol and chloroform, acidulated with acetic or hydrochloric acid have given good results in some cases, but the proportions and method which will give uniformly satisfactory results have not yet been discovered.

PARKE, DAVIS & Co., Detroit, Mich.

DISCUSSION.

Otto Raubenheimer, of Brooklyn, said Mr. Scoville's work was certainly a valuable one, and proved without doubt that the Brussels International Conference had made a mistake when they made the international agreement that tincture of cantharides should be made 10 percent strength. Instead of using a menstruum of 70 percent alcohol by percolation, Mr. Scoville recommended making a glacial acetic acid menstruum, which seemed to extract the cantharidin and made a 100 percent tincture, by mixing one part of glacial acetic acid with nine parts alcohol. He thought this was a good means of extracting the cantharides. But at the same time it was doubtful whether it could be used, because frequently tincture of cantharides was administered internally, and especially as a veterinary remedy, for horses and cattle. He thought this formula was objectionable because of its high percentage of glacial acetic acid.

Mr. Scoville responded to this that in the official dose of tincture of cantharides the equivalent would be given. For instance, 5 minims tincture cantharides made with acetic menstruum equals 8 drops of ordinary vinegar; so even with a horse or other animal, where a relative amount was given, he did not see how it could be objectionable.

F. T. Gordon, of Philadelphia, wanted to know the effect of cantharides used as a hair tonic, and Mr. Scoville responded humorously that it was "a psychological effect only," inasmuch as there was no cantharidin really in these remedies.

L. F. Kebler, of Washington, D. C., wanted to know of Mr. Scoville on what basis he made the statement that the present pharmacopœial tincture of cantharides was misbranded, in view of the fact that this was recognized as standard in the Federal Food and Drugs Act? The law declared that if it was prepared in accordance with the pharmacopœial method, it was a proper standard. He remarked that the results here stated brought to mind the possible reason why so many hair-tonics, said to be made with cantharides, had failed. He thought it was worth while to investigate this subject, for the benefit of mankind in general.

DETERMINATION OF SANTONIN IN SANTONICA.

CHARLES E. CASPARI, ST. LOUIS.

During the past winter, the fact was brought to my attention that Santonica was being bought and sold on its santonin assay, in fact, a certain manufacturer of stock remedies was in the market for Santonica with a guaranteed santonin content, claiming that he had always been able to procure such. At that time I knew of no published method for the determination of santonin and after correspondence and conversation with a number of my pharmaceutical-chemical friends, I learned that they knew no more than I did about the determination of santonin. I discovered that a firm of crude drug dealers in Chicago was assaying Santonica, but when I applied to that firm and requested it to give me

the method of assay, my request was politely but firmly refused, on the ground that this firm intended to take up the manufacture of *santonin* on a large scale and that its assay method would be the manufacturing process, which it desired to keep secret. About this time, our presiding officer, Mr. Frank R. Eldred, whom I take this opportunity of thanking, as well as the firm with which he is connected, Eli Lilly & Co., called my attention to three articles published in the *Archiv der Pharmazie* by Thaeter in Vol. 235, page 401 and Vol. 237, page 626 and by Katz in Vol. 237, page 245. Katz's article is a criticism of Thaeter's first article and some suggested improvements and Thaeter's second article is a reply to Katz.

I carefully and conscientiously endeavored to apply both the methods of Katz and Thaeter to the determination of *santonin*, but with very unsatisfactory results. Some *santonin* was always obtained, but an indeterminate amount was always lost on account of the large amount of resin that was precipitated with the *santonin* and the difficulty of separating the *santonin* quantitatively from the resin, so that it was impossible for me to obtain duplicate results that checked. About this time, my father, Charles Caspari, Jr., referred me to an article by Fromme, published in the *Jahres-Bericht* of Cäsar & Loretz of Hallé for September, 1912, for the determination of *santonin* in *Santonica*, which is a modification of Katz's method and which gave very satisfactory results. I take this occasion to say that I make absolutely no claim of originality in this paper, but merely desire to call the attention of the pharmaceutical-chemical profession to a quantitative method which I am sure is little known and which gives good results.

The method of Fromme follows: Thirteen grams of moderately finely powdered wormseed are placed in a separatory funnel containing 130 grams of chloroform. A pledget of cotton should be placed in the funnel above the stopcock before introducing the wormseed. After one hour's maceration with occasional shaking, 102.5 grams (equal to 10 grams of drug), of the liquid are drawn off into a 200 c. c. Erlenmeyer flask. Evaporate the chloroform until the residue weighs 7 to 8 grams. Add 100 grams of five percent barium hydroxide solution and place the flask in hot water. After the chloroform has evaporated sufficiently to enable the resin to rise to the surface, it is heated until all odor of chloroform has disappeared. Filter through a plain filter of six cm. diameter, previously wetted, into a 200 c. c. Erlenmeyer flask; rinse the flask and filter twice with 10 c. c. of hot water, add five grams of twenty-five percent hydrochloric acid to the filtrate and heat the whole for several minutes on a boiling water bath. After the liquid has been cooled somewhat by setting the flask in cold water, pour the liquid into a separatory funnel and rinse the flask with twenty c. c. of chloroform, which is added to the contents of the funnel. Shake the mixture actively for two minutes and after the chloroform has separated perfectly, filter the same through a double plain filter into a 100 c. c. Erlenmeyer flask. Wash the acid-aqueous liquid twice with fifteen c. c. of chloroform by agitation and draw the chloroform off as before through the filter. Distil the chloroform from the combined filtrate and remove the last traces of chloroform from the residue by a current of warm air. Dissolve the residue in 7.5 grams of absolute alcohol and add 42.5 grams of hot distilled water. Filter the milky

liquid at once into a tared 100 c. c. Erlenmeyer flask and wash the flask and filter twice with ten grams of a mixture of three grams of absolute alcohol and seventeen of distilled water. Set the filtrate aside for 24 hours (not longer) and filter through a plain six cm. tared filter, washing the flask and filter twice with ten grams of the above alcohol-water mixture. Dry the flask and filter at 100 degrees C. to constant weight, place in a desiccator for one-half hour and weigh again. To the weight of the santonin thus found add 0.04 gram for loss by solution in the dilute alcohol. The total weight of santonin multiplied by ten, gives the percentage content, which should be calculated on the basis of previously dried wormseed.

It may not be out of place to say a word in explanation of Fromme's method. Santonin is the inner anhydride or lactone of santonic acid and probably occurs as such in the wormseed. The extraction with chloroform removes the santonin and considerable resin, while the treatment with barium hydroxide converts the santonin into barium santoninate, at the same time that the barium salt of certain resin acids is formed. The addition of hydrochloric acid sets free santonic acid and also some resin acids. The heating on the water bath for several minutes serves to convert the santonic acid into the lactone, santonin. This, together with some resin acids, is extracted from the acid liquid with chloroform and the chloroform is then evaporated. The residue is dissolved in absolute alcohol and enough hot water is added to make the alcohol fifteen percent strength, because it was found by experiment that alcohol of this strength was best adapted to dissolve the santonin while hot and to hold the least amount in solution when cold. When the alcoholic solution cools, the santonin separates out in crystals, while the resins separate out in such a fine state of division that they pass through the filter paper with the greatest ease. The addition of 0.04 gram to the amount of santonin obtained is made necessary because that amount of santonin is held in solution by the amount of fifteen percent alcohol used. In order to obtain concordant results, it is necessary to adhere rigidly to the amounts given in the method.

I have tried this method on two samples of *Santonica*, and, as stated above, I obtained very satisfactory results. The method is infinitely superior to that of either Thaeter or Katz. The results which I obtained on the two samples of *Santonica* were Sample No. 1, 2.09% and 2.21% and Sample No. 2, 2.46% and 2.33%. I have not had time to make more determinations, but the method worked so satisfactorily that I see no reason why it should not prove successful in the hands of any chemist.

In Vol. II, page 596, of the *Journal of the American Pharmaceutical Association*, LaWall calls attention to the fact that there is *Santonica* on the market which is practically devoid of santonin, and I wish to confirm this fact. There are large quantities of wormseed being imported into this country, in which the amount of santonin cannot be considered as more than the faintest trace and it is practically impossible to differentiate by inspection between the true and the spurious. Hence, it becomes necessary to have recourse to the quantitative method for the determination of santonin and fortunately we have a satisfactory method in the one of Fromme described above. It would seem desirable that this method be adopted by the government at the various ports of entry of this

country and that it also be incorporated in the forthcoming United States Pharmacopœia.

ANALYTICAL LABORATORY, MEYER BROS. DRUG CO., St. Louis.

DISCUSSION.

Clement B. Lowe, of Philadelphia, said that large quantities of crude santonin were being imported into this country, and he wanted to know whether it was possible that this *santonica* which seemed to yield no santonin had been treated, or could be treated, without altering the physical appearance of the drug. He was aware that this had been done with some drugs, as with opium, for instance, where a part of the morphine content had been abstracted and then the drug fixed up from that.

Prof. Caspari said it was true, that large quantities of crude santonin were imported, but the source was controlled by the Russian government, a close corporation, and he did not believe that the *santonica* that came in devoid of santonin had been subjected to treatment in the old country. Dr. H. H. Rusby had told him that the spurious article was a different species. Tons of this spurious species were being used all over the country, especially for stock-powders, which were absolutely worthless.

Hermann Engelhardt, of Baltimore, made the comment that out of ten samples of *santonica* he had examined, he had found nine with no trace of santonin whatever. He expressed the opinion that all of the tests given were uncertain.

Chairman Eldred said that, while it did not bear upon the determination of santonin, he was reminded to say that the representative of a drug importer had told him a few months before that he had considered the handling of santonin, and had gone to Russia to investigate the conditions of the market there, and he had found it just as Mr. Caspari has stated, that it was a very close corporation. An interesting fact was, that some of the growers were paid for their drug, which was then set fire to and burned in the fields, in order to keep from overloading the market with santonin.

DETECTION AND ESTIMATION OF MINUTE QUANTITIES OF FORMALDEHYDE IN PRESENCE OF HEXAMETHYLENAMINE AND OF METHYL ALCOHOL IN PRESENCE OF ETHYL ALCOHOL.

H. A. B. DUNNING, BALTIMORE.

Sometime during the year 1912, Dr. Curtis F. Burnam, member of the staff of Johns Hopkins Hospital, sought my advice as to the most satisfactory method of detecting traces of formaldehyde in urine.

After a careful investigation, I recommended, as most delicate and satisfactory, three tests herein named and described.

Only one of these tests, Rimini's, was of particular value in his work on account of the presence of hexamethylenamine in the material tested. Hehner's milk test, while most delicate, was not suitable on account of being conducted in acid solution, resulting in decomposition of hexamethylenamine with the production of formaldehyde.

While Rimini's test has been found to be most satisfactory in differentiation of formaldehyde in presence of hexamethylenamine, experience teaches that certain precautions should be observed to obtain best results.

The specimens to be examined and all test solutions should be warm, not hot.

and an excess of nitroprusside solution should be avoided. In weak specimens the nitroprusside solution should be diluted five to ten times. In urine, formaldehyde may be detected readily by this test in strength of 1-100,000; in weaker strengths than this, much depends upon the care and experience of the operator.

The test is usually conducted as follows: About 2 cc. of urine specimen, contained in five inch tube, is warmed and two drops of one-half percent fresh solution of phenylhydrazine hydrochloride is added, followed by two drops of one-half percent fresh solution of sodium nitroprusside, the mixture being made strongly alkaline with saturated solution of sodium hydroxide. In strengths 1-20,000 to 1-50,000, deep blue colorization results, changing in a few minutes to green, then yellow, or perhaps, red. In more dilute solutions the blue lasts momentarily only, and is quickly succeeded by green. The blue may be made to last longer and become more distinct by adjustment of the quantities of sodium nitroprusside and phenylhydrazine hydrochloride added, the weaker strengths requiring less nitroprusside and phenylhydrazine. In alkaline solutions phenylhydrazine gives a yellow color, therefore, if there is but a trace of formaldehyde the blue color is masked and converted into green by mixtures of blue and yellow.

The Phloroglucin test, the author of which I have lost record, is quite satisfactory for dilutions of formaldehyde in urine, not exceeding 1-100,000, the red color being masked by yellow of the urine. The author of this test directs that a solution of phloroglucin, 1 gram, alcohol 90 percent, 100 cc. and sodium hydroxide 10 grams, be made fresh. A much better plan is to prepare a solution of phloroglucin in alcohol 1 gram to 100 cc. and add strong solution of sodium hydroxide to specimen at time of testing.

The test is conducted as follows: To 2 cc. of specimen, previously warmed, contained in a five inch test tube, add one drop of alcoholic solution of phloroglucin, then make strongly alkaline with saturated solution of sodium hydroxide, previously warmed. The color produced is red.

These tests have been used with satisfaction in connection with an investigation made by Dr. Burnam and his associates. It seems to me desirable, in connection with this paper, to call attention to the character of Dr. Burnam's work and the importance of the conclusion arrived at.

Dr. Burnam has learned that small doses, as little as five grains per day, of hexamethylenamine may produce formaldehyde in the urine of strength exceeding 1-30,000, this being highly destructive to the mucosa of the bladder, while in other patients or, perhaps, at different times, one hundred grains per day will produce only traces of formaldehyde, or perhaps, none at all. The point of interest is that it is dangerous to give large doses of hexamethylenamine until the patient has first been treated with small doses.

Subsequent to the publication of Dr. Burnam's paper, much interest was evinced by the medical fraternity in the discovery of a test for the quantitative estimation of formaldehyde in the urine that would differentiate hexamethylenamine and yet would be practicable in the hands of the physician.

I offer the following test to fill this requirement: From an assayed specimen of commercial formaldehyde solution, accurate dilutions are prepared of strengths 1-50,000, 1-100,000, 1-200,000, 1-300,000, as standard solutions for

colorimetric comparison. More standard solutions may be prepared if necessary. The test will estimate quantitatively up to 1-500,000 in the urine and 1-30,000,000 in clear water. Dextrose, acetone, acetaldehyde do not interfere in solutions weaker than 1-30,000 and then only on heating or long standing.

The test is conducted as follows: To five cc. of the specimen contained in a five inch test tube, add .1 cc. of 15 p. c. solution of sodium hydroxide and mix well. Then add .1 cc. phenylhydrazine base, not hydrochloride, finally add .7 gram of stick sodium hydroxide and agitate for ten minutes. The strength is estimated colorimetrically by comparing with the standard solutions treated in same manner as specimen, and at the same time. It is important to remember that the several reagents must be added to specimen and standard solutions at the same time; i. e., specimen and standard are treated simultaneously.

Colorimetric comparisons must be made within twenty minutes after stick alkali is added. Usually comparisons are made in about ten minutes subsequent to the addition of stick alkali.

If it is desired to keep specimens for some hours previous to estimation, then the .1 cc. of 15 p. c. solution of sodium hydroxide must be added. This precaution prevents decomposition of hexamethylenamine with production of formaldehyde, which will take place in acid urine on standing. After specimen has been made alkaline as directed in method of assay, no attempt should be made to remove precipitate, as such procedure will remove free formaldehyde wholly or in part. In my experience any attempt to remove color of urine, by charcoal, precipitation, reduction, oxidation, etc., results in removal of some or all of free formaldehyde.

This test has been used with much satisfaction in a series of clinical experiments conducted at the Union Protestant Infirmary by Dr. George Walker, associate professor of Surgery, Johns Hopkins Hospital.

In line with the above work is a recent examination of samples of whiskey submitted by Dr. Hiram Woods, Eye Specialist, of this city. Dr. Woods stated that he was at that time treating a patient almost blind, who could offer no explanation of his condition except that he had partaken rather freely of whiskey mislabelled Sherwood Maryland Rye.

Upon investigating a sample of this brand of whiskey it was found to be a mixture of approximately 30 percent methyl alcohol, about 15 percent grain alcohol and 55 percent water. This sample was tested among other tests, including specific gravity of distillates, as follows:

A test tube partially filled with the sample was heated until vapor formed in upper part of tube, into which a copper spiral heated to redness and slightly cooled in air was plunged. The characteristic odor of formaldehyde and the effect on nasal passages was observed, masked to some extent by acetaldehyde and other odors. The formaldehyde odor was much more characteristic when applied to a fraction of distillate partially freed from water by saturating with potassium citrate and distilling the supernatant layer.

The specimen was further tested as follows: 100 cc. was supersaturated with potassium citrate and thoroughly shaken, when two strata of liquid were formed, the upper measured about 44 cc. This latter liquid was removed into a distilling bulb connected with a distillation tube having several bulbs and carrying glass

beads. The liquid was heated on water bath and began to boil at 68°-70° C., the larger portion distilling over under 75° C., rising to 78° then to 85°. The mixed distillate was twice distilled over lime, practically all coming over under 78° C. This distillate was then carefully fractionated, the lower boiling fractions being collected and refractionated until 19 cc. of liquid boiling at 60°-66° C. was obtained. This distillate tested with the copper spiral gave entirely characteristic formaldehyde effects.

Formaldehyde produced in solution by plunging a heated copper spiral into portion of distillate and testing in accordance with Rimini's Test, gave entirely characteristic reaction, as also Hehner's milk test, the phloroglucin test, and Dunning's test.

Methyl salicylate was produced with salicylic acid and sulphuric acid, but only a trace of iodoform could be produced. The quantity of methyl alcohol, 96 percent, was then estimated with a refractometer and by the method suggested by C. Simmonds in his notes on the determination of small quantities of methyl alcohol,* which are here given:

"Small proportions of methyl alcohol have hitherto been somewhat difficult to determine readily and accurately. Fairly good approximate results can be obtained by comparative experiments with the well known method of Riche and Baddy (*Compt. rend.*, 80, 1076 [1875]), or with Wolff's modification of Trillat's process (*Ann. Inst. Pasteur*, 1912, 8), but these methods are lengthy and rather troublesome. The process described by Thorpe and Holmes (*J. Chem. Soc.*, 85, 1 (1904), gives good results when the quantity of methyl alcohol is not too small. It is not well adapted, however, for use when the proportion of methyl alcohol is less than about 2 percent of the ethyl alcohol, since the necessary subtractive correction (*loc. cit.*, pp. 2, 3) may in such cases be equal to or may exceed the quantity it is desired to estimate. For determining very small portions of methyl alcohol the method is quite inapplicable. In such cases satisfactory determinations can be made by applying the principle of colorimetric comparison by Deniges' process for detection of methyl alcohol (*Compt. rend.*, 150, 332 [1910]).

"The possibility of thus using the process is indicated by Deniges, (*loc. cit.*, p. 833). The object of the present note is to give the procedure which the writer finds most suitable for utilizing the reaction quantitatively in general analytical work, as, for example, in examining spirituous beverages, medical tinctures, flavoring essences, and so forth.

"The alcoholic mixture is best purified, when necessary, either by the method of Thorpe and Holmes (*J. Chem. Soc.*, 83, 314 [1903]), or by other suitable means. It is then diluted with water or mixed with ethyl alcohol, as the case may require, until it contains 10 percent of total alcohol by volume.

"To 5 cc. of this prepared liquid contained in a wide test tube are added 2.5 cc. of permanganate solution (2.0 grams KMnO_4 per 100 cc), and then 0.2 cc. of strong sulphuric acid. When the reaction has proceeded about five minutes, 0.5 cc. of oxalic acid solution is added (0.6 grams crystallized acid per 100 cc.). On shaking the liquid becomes clear and nearly colorless. One cc. of strong sulphuric acid is now run in and well mixed with the solution, which is finally treated with 5 cc. of Schiff's reagent. A violet color is developed in the course of a few minutes unless mere traces of methyl alcohol were present, when twenty or thirty minutes may be required.

"This color is due, of course, to the reaction of the fuchsin solution with formaldehyde, produced by the oxidation of the methyl alcohol. A sufficient quantity of sulphuric acid is present to prevent the development of color with any acetaldehyde formed from the ethyl alcohol during the oxidation.

*Government Laboratory, London. *Analyst* 27, 16 (1912).

"A preliminary experiment carried out as described serves to detect the presence of methyl alcohol, if it is not already known, and to give some idea of the quantity. According to the indications thus obtained, another part of the prepared liquid is further diluted, if necessary, with ethyl alcohol of 10 percent strength until it contains from 0.001 to 0.004 grams of methyl alcohol in 5 cc.; the experiment is repeated side by side with two or more standards for comparison. These contain 0.001, .002, 0.003, etc., gram of methyl alcohol in 5 cc. of 10 percent ethyl alcohol. The colors produced are compared in small Nessler tubes (25 cc.) or in a suitable colorimeter.

"With properly sensitive Schiff's reagent, 0.0003 gram methyl alcohol in the 5 cc. of liquid taken is readily detected. The best depths of color for comparison, however, are given by the formaldehyde produced in the manner described from quantities of 0.001 to 0.004 gram of methyl alcohol.

"It is convenient to keep a standard solution (1 gram per liter) of methyl alcohol in 10 percent ethyl alcohol. This is diluted as required with 10 percent alcohol to form the standards for comparison. This proportion of ethyl alcohol (10 percent) is a suitable strength for general work, as the distillates ordinarily obtained are stronger, and can be diluted down instead of having to be concentrated.

"The process has the advantage of (1) being rapidly executed, (2) requiring only a small quantity of material, and (3) being directly applicable to weak distillates. The degree of accuracy obtainable is shown by the following results of a typical series of experiments:

		Grams methyl alcohol per 100 cc.					
Present0.005	0.028	0.044	0.072	0.100	0.500	1.000
Found0.004	0.029	0.046	0.072	0.104	0.492	0.968

"Formaldehyde, of course, must be absent from the unoxidized solution of the alcohols, or else its effect must be determined and allowed for. Glycerol must also be absent."

The method of purification referred to is for the purpose of getting rid of other volatile substances, such as ether, chloroform, benzene, essentials oils, etc. Twenty-five cc. of the sample are diluted in a separatory funnel with water to 100-150 cc., enough salt added to saturate the solution which is then shaken vigorously for five minutes with 50-80 cc. of light petroleum (boiling below 60°), allowed to stand 0.5 hour, the lower layer drawn off and again extracted if necessary, the petroleum extracts washed with 25 cc. of saturated salt solution, the wash waters added to the main bulk of liquid which is then neutralized if necessary and 100 cc. distilled over. Experiment has shown that all of the alcohol is recovered in the first 100 cc. of distillate.

Sensitive fuchsin bisulphite solution is readily made according to the following formula: In 100 cc. of a saturated solution, less than 1 percent of basic fuchsin, dissolve sodium bisulphite 10 grams and when nearly colorless mix with purified animal charcoal and filter; a perfectly clear solution should result.

DISCUSSION.

Otto Raubenheimer, of Brooklyn, said that hexamethylenamine should be taken internally with caution, as he had learned by an experience in his own family, where the hexamethylenamine, instead of being taken three times a day, in five-grain doses was taken every hour. After the patient had taken five doses she was thrown into a great state of excitement, with impairment of vision, and it was necessary to call in a physician. This experience had

proven to him that hexamethylenamine should be taken inwardly with great caution. He thought that one thing might be stated in the paper by way of caution—a fact well known to chemists—that phenylhydrazine and sodium nitroprusside solutions should be freshly made, as they deteriorated very rapidly and that they should furthermore be protected from light.

METHODS OF ANALYSIS FOR CERTAIN PHARMACEUTICAL PREPARATIONS.

LINWOOD A. BROWN, PH. C., PHAR. D., LEXINGTON, KY.

In the course of a year's work in a laboratory devoted to the analysis of drugs and drug preparations, it often becomes necessary to devise new methods, or to modify old ones, for the analysis of certain drug products that do not have any commonly recognized methods.

So far as the author is aware, the following methods have not appeared in print, and my reason for calling your attention to them is the fact that perhaps someone else may have need for such methods.

DETERMINATION OF MORPHINE IN TABLETS.

Take a sufficient number of tablets to equal about four or five grains of morphine, place in a small Erlenmeyer flask of about 50 cc. capacity, add 10 cc. of water and a drop of dilute sulphuric acid and allow to dissolve. If the tablets are not entirely soluble, as determined by a previous test, place the powdered tablets in a 5.5 cm. plain folded filter and extract with distilled water, applied drop by drop, using if possible not more than 10 to 15 cc. of water.

Now add a few drops of cochineal or methyl red and sufficient ammonia to give neutral point, and then add $\frac{1}{2}$ to 1 cc. of 10% ammonia in excess.

Place sample in an ice chest, preferably resting upon a cake of ice and allow to stand over night, when if precipitation has taken place properly, the morphine will appear as a fine crystalline precipitate. Filter into a weighed Gooch crucible, wash well with cold water, dry at 65° C. and weigh.

Place filtrate from above in a separatory funnel and extract five or six times with 30 cc. portions of a mixture of chloroform 3 parts, and alcohol 1 part, being careful to maintain a very slight excess of ammonia. Wash the united chloroform-alcohol solution of morphine twice with 5 cc. portions of water, and then extract the aqueous washings with an equal volume of chloroform.

Filter the chloroform-alcohol solution of morphine through a small filter wetted with chloroform, into a suitable flask and distill off all but about 10 cc. of the liquid, evaporate the remaining portion to dryness on the water bath, take up in neutral alcohol (2 or 3 cc.) add an excess of N/50 sulphuric acid (about 15 cc.), a few drops of methyl-red or cochineal as indicator and titrate excess of acid with N/50 KOH. Each cc. of N/50 acid consumed is equal to 0.006 gm. crystallized morphine.

Add weight of morphine found in filtrate by titration to that obtained by

gravimetric method and multiply this figure by 1.251 to get amount of morphine sulphate in sample used.

ASSAY OF EFFERVESCENT SOLUTION OF MAGNESIUM CITRATE.

In addition to such tests and observations as appearance, odor, precipitate, if any, gas pressure, sp. gr. at 25° C., volume of entire sample, sulphates, chlorides, etc., we make the following assay:

Free Citric Acid.

Having first determined the total volume of the sample, measure out exactly 15 cc., add an equal volume of water, and boil until free from CO_2 , cool, add a few drops of phenolphthalein, and titrate with $\text{N}/2$ KOH .

Each cc. $\text{N}/2$ KOH = .03475 gm. citric acid.

Total Citric Acid.

Evaporate the liquid remaining after determining "free citric acid" to dryness in a platinum dish, char thoroughly, take up residue in 20 cc. $\text{N}/1$ H_2SO_4 , heat on water bath, filter through ashless filter, and wash filter thoroughly with hot distilled water, burn filter in same dish, and dissolve the small amount of ash in a portion of the filtrate, filter if necessary, wash thoroughly, cool, and titrate excess of $\text{N}/1$ H_2SO_4 with $\text{N}/2$ KOH , using methyl orange as the indicator.

Each cc. $\text{N}/1$ H_2SO_4 consumed = .0695 gm. total citric acid.

Each bottle of Solution Magnesium Citrate when made by the U. S. P. formula should contain 33.6 gm. U. S. P. citric acid, and 15 gm. magnesium carbonate, equivalent to not less than 5.76 gm. pure MgO , and 2.5 gm. potassium bicarbonate.

According to my calculations, we should have in a strictly U. S. P. preparation, 11.87 gm. free citric acid, 21.73 gm. combined citric acid, and 5.76 gm. MgO per bottle.

Determination of MgO .

Dilute 25 cc. of the sample with water to 100 cc. Measure out 25 cc. aliquots, place in wide mouthed Erlenmeyer flask, and determine MgO by A. O. A. C. method as given in Bulletin 107, revised, page 16.

Calculate to gm. MgO per bottle.

By means of the above method we obviate the disagreeable feature of precipitating the citrate as the lead salt and its subsequent manipulation as proposed by Street. (Report of Conn. Agric. Exp. Station, 1912, part 2, page 165.)

ASSAY OF SEIDLITZ POWDERS.

Weight of Powders.

Weigh each powder in the box, using as counterpoise a powder paper of the same kind used in sample, compute the average weight of both the "white" and "blue" powders, reporting maximum, minimum, and average weight.

Assay of "Blue" Powders.

(1) Determination of Sodium Bicarbonate. Place one or two of the "blue" powders in a mortar and reduce to very fine powder to thoroughly mix, transfer to weighing bottle, and weigh off duplicate samples of about 1.5 gm., transfer carefully to flask, add about 50 cc. of water and 10 cc. $\text{N}/1$ sulphuric acid,

and boil until free from CO_2 , cool, add phenolphthalein and titrate excess of acid with N/1 KOH.

Each cc. N/1 sulphuric acid consumed equals 0.08343 gm. sodium bicarbonate.

(2) *Rochelle Salt*. Weigh off samples of exactly the same amount as were used in the bicarbonate determination, place in platinum dish and carefully ignite until all organic matter is thoroughly charred, cool, and thoroughly extract ash with hot water, filter, burn filter and dissolve residue, if any, in water and add to previous solution. Aqueous solution should be colorless and perfectly clear, otherwise sample has not been ignited enough and determination must be repeated. Add methyl orange to aqueous solution and titrate to neutrality with normal sulphuric acid.

Calculation. Owing to the fact that the soda bicarbonate has been determined along with the Rochelle salt in this method, a correction must be made for it.

If samples of the same weight have been used, subtract the amount of acid consumed in the bicarbonate determination, from the amount used in the last assay. This will give the amount of acid consumed by the alkalinity of the ash due to the Rochelle salt.

Each cc. N/1 sulphuric acid consumed in this determination after allowing for the bicarbonate is equivalent to 0.14009 gm. Rochelle salt U. S. P.

The "blue" powder should weigh 10.33 gm. and should contain 25% sodium bicarbonate and 75% Rochelle salt. Each "white" powder should weigh 2.25 gm. net, and consist of tartaric acid U. S. P.

TINCTURE OF IODINE.

It would seem, after all that has been said and written concerning this preparation, that little remains, however I wish to call your attention to a few methods that have given satisfaction in my hands.

Determination of Alcohol. A number of methods of procedure have been suggested for this determination, such as shaking with metallic mercury until iodine is decolorized, (Alcock, Proc. A. Ph. A., 1904, p. 583); adding sodium thiosulphate in slight excess and distilling from an alkaline solution, (Gane & Webster Chem. Abs., vol. 3, p. 2487); and Cameron (Analyst, 1902, p. 87), who suggests in place of caustic soda the use of iron filings.

As I have never seen the following method suggested I take the liberty of doing so, especially as the above mentioned methods have certain objections, such as slowness of action between the iodine and the mercury or iron filings, difficulty of distilling from an alkaline solution, contamination of distillate with iodoform and other volatile substances, etc.

Place about 70 cc. of distilled water in a 300 cc. Erlenmeyer flask, add about 1 gm. of "zinc dust" such as is used in Kjeldahl method for nitrogen, or sufficient to leave a decided excess after combining with the iodine, now add exactly 10 cc. of the tincture, observing the proper precautions as to temperature in measuring out sample, shake flask, and immediately connect up with a good condenser, worm condenser preferred, and provided with an efficient spray trap, and distill over nearly 50 cc. of distillate.

Make up to volume with distilled water at desired temperature, and determine

sp. gr. of distillate by means of a pycnometer, and from the sp. gr. thus obtained calculate the percent of alcohol.

The zinc dust serves two purposes, first it *immediately* combines with the iodine forming a colorless solution of zinc iodide, and second, the excess of zinc helps to make the solution boil smoothly.

Determination of Free Acid. After the titration of the iodine as in the U. S. P. method, add a few drops of phenolphthalein to the clear liquid and run in decinormal KOH until liquid has faint pink color. The use of starch solution in the determination of the iodine is not necessary, as the change from the yellow color of the iodine to the colorless solution is quite distinct, and the use of the starch paste interferes with the "free acid" titration.

In samples made with the full amount of potassium iodide, it should not require more than one or two drops of 1/10 normal KOH, while in a tincture made without potassium iodide, and a few weeks old it sometimes requires as much as 5.75 cc. of the solution for a 5 cc. sample, equivalent to 1.459 gm. absolute hydriodic acid per 100 cc. of tincture. Each cc. of decinormal KOH consumed equals 0.01269 gm. HI.

This process depends upon the fact that the products of the reaction between iodine and sodium thiosulphate are neutral, and the free hydriodic acid can be titrated with standard alkali.

Determination of Potassium Iodide. Measure out 10 cc. of sample into a weighed porcelain dish, and place on top of water bath, but not in direct contact with steam, and set fire to the alcohol vapors to prevent the iodine creeping over the edge of the dish. Allow to evaporate to dryness, moisten a few times with 2 or 3 cc. of dilute alcohol, evaporating to dryness each time, finally ignite at a low temperature, short of red heat, cool and weigh. Calculate grams potassium iodide per 100 cc.

This is essentially the same method as proposed by Lawall (Proc. A. Ph. A., 1907, p. 159) and is given here with a few modifications, simply to call attention to it as a satisfactory method for this determination.

Theoretically potassium iodide is the only non-volatile ingredient of tincture of iodine, though the iodine and alcohol may contain small amounts of non-volatile matter, sufficient to sometimes give a dark gray color to the residue. This, however, is not sufficiently great ordinarily to seriously interfere with its accuracy as a practical method. In case the residue is very impure, it should be dissolved in water and the iodide determined in the residue by means of Volhard's method.

DETERMINATION OF TOTAL ARSENIC IN FOWLER'S SOLUTION.

Owing to the fact that arsenic has a tendency to oxidize in alkaline solution, during the process of manufacture, or by age, it becomes necessary to know the total amount of arsenic present as well as that in the arsenious condition.

Weigh out sample of about 15 cc., add 5 cc. of dilute sulphuric acid (1:3) and 1 gm. of potassium iodide, dilute to 100 cc. and boil down to about 40 cc.; cool, add starch solution and remove excess of iodine by the careful addition of thiosulphate solution, neutralize excess of acid by the addition of sodium bicarbonate, and add 2 or 3 grams in excess.

Determine arsenic from this point by the U. S. P. method. The difference between the percent of As_2O_3 by the U. S. P. method and "total arsenic" calculated as As_2O_3 represents the amount of arsenic in oxidized form.

DISCUSSION.

Philip Asher, of New Orleans, referring to the method proposed by Mr. Brown of using both the gravimetric and the volumetric processes, asked, "Why not stop at the volumetric, and get the morphine content?" Referring to the author's method of determining the alcohol in iodine, he said he had used that method himself, and it was approximately correct, sufficiently so for all practical purposes, and it could be carried out in two minutes. He placed some alcohol in a graduated cylinder and added potassium carbonate. This was shaken thoroughly, and in a short while the alcohol was found lying out above the potassium carbonate, upon which he was making the determination.

Continuing, Mr. Asher said, referring to the author's determination of free acids by distillation, that, in the early '90s, he had carried on a series of experiments of this kind, and had gotten his free acids by determining the free iodine by the potassium iodate method. He started by adding sodium thiosulphate until all the free iodine was taken up, and then added a small amount of potassium iodate. The iodate, in the presence of hydriodic acid was split up into iodine. The number of cubic centimeters found, multiplied by five-sixths, and by the iodine coefficient gave the iodine that was converted into hydriodic acid. This gave an exact determination. The desired result was had, without going through the process of distillation.

Mr. Brown responded that in the determination of morphine by precipitation, and extraction of the residual morphine left in the "mother liquor," he got around the disadvantage of having to use a large amount of solvent, which would be necessary if *all* the morphine was extracted by means of an immiscible solvent.

He did not determine the "free acid" by distillation as had been suggested. If the titration method was used, all that was necessary to do was to add a little phenolphthalein indicator to the solution, after decolorizing with thiosulphate, and titrate with tenth normal alkali to get the free acid, the product of the reaction between the thiosulphate and the iodine being neutral.

THE STABILITY OF OUABAIN IN AQUEOUS SOLUTION.

CHAS. C. HASKELL AND W. A. DOEPPERS.

Galenical preparations and isolated pure principles of digitalis are comparatively slowly absorbed when administered by mouth to normal individuals. In patients suffering from cardiac disease, a condition of acute circulatory embarrassment often occurs, rendering it of the greatest importance to secure prompt drug action; but the venous stasis dependent upon the circulatory failure gives rise to engorgement of the gastro-intestinal mucosa and consequently, further delays absorption by this route.

In the treatment of such patients, clinicians have long desired some remedy that could be introduced directly into the blood stream and bring about full and prompt action. The infusion of digitalis has been employed in this way, but it would seem that it would be desirable to study upon lower animals the effect of

introducing the number of undesirable constituents present in crude preparations of digitalis before the use of the infusion in this manner could be unqualifiedly endorsed. Then too, the experiments of Hatcher and Eggleston have shown that the commonly held opinion regarding the instability of the infusion is fully justified. Finally, it would be hard to secure an estimate of the strength of crude preparations of digitalis sufficiently accurate for use in standardizing remedies for intravenous use.

Credit is due to Hatcher for drawing attention to the possible value of Strophanthin gratus; known as crystalline Strophanthin, Thoms; or better, as Ouabain. This substance is a crystalline glucoside, isolated from Strophanthus gratus; probably a definite chemical compound; and is readily soluble in water or alcohol.

Amorphous strophanthin has been used quite extensively for intravenous administration; and the results have often been very favorable. The chief disadvantage in the use of this substance is the uncertainty concerning its composition, it being probable that it is a mixture of different glucosides and different lots are apt to vary in strength.

Ouabain in a dry condition kept under ordinary climatic conditions, exposed to air and light, undergoes no change in two years that can be detected by animal experiments. The convenience afforded by offering the physician a solution of Ouabain in ampoules, has led us to undertake a study of its keeping qualities when dissolved in solutions of different composition.

Ouabain was dissolved in distilled water, in normal salt (.09%) solution; in 5 percent alcohol; in 10 percent alcohol; in 25 percent alcohol and in 95 percent alcohol. The ouabain percentage was 1/10 to 1/100. Some of these solutions were tested upon frogs, using Cushny's one hour method; others upon guinea pigs, using a 24 hour lethal dose method; and a few upon cats, using Hatcher's method. The frog and cat methods have already been fully described elsewhere. The guinea pig method is a modification of Reed's. The dose is calculated per gram body weight and injected subcutaneously as in Reed's method. We have found it necessary, however, to take account of the alcoholic content of the solution and also advisable always to use the same volume of fluid per gram, so 0.01 cc. fluid per gram weight is always injected and 25 percent alcohol has been used in all the tests. It is also more satisfactory to observe the animal for 24 hours, because it is very common for pigs to survive more than three hours and succumb before the expiration of twenty-four hours. Occasionally, an animal succumbs only at the end of forty-eight hours, but this is unusual. Attention has already been called to the unreliability of the guinea pig method in attempting to standardize the members of the digitalis group, but in a comparative study such as this the factor of seasonal variation does not enter. The results may be tabulated as follows: "Drug strength means the strength of the original solution, which was reduced to 1:100000 for the cat assay; 1:20000 for the frog assay; and 1:10000 for the guinea pig assay whenever it was originally stronger. The figures under cat assay are fractions of a milligram per kilo; under guinea pig and frog assay are fractions of a gram per gram.

I. OUABAIN IN AMBER GLASS CONTAINERS.

Age of Solution	Solvent	Drug Strength	Container	Cat Assay	Guinea Pig Assay	Frog Assay
2 days	95% Alc.	1:1000	Flask	.0788	.00000025	.00000045
9 months	Water	1:10000	Amber Bottle00000025	.00000045
14 months	Water	1:10000	Amber Bottle	.0800	.00000025	.00000046
28 months	Normal Salt	1:1000	Amber Bottle	.0796	.00000027	.00000046

From these results it may be assumed that Ouabain dissolved in distilled water or in normal salt solution and kept in amber bottles suffers no appreciable loss of strength in 28 months.

Two samples had been kept in glass-stoppered flint bottles and the assay of these give rather surprising results.

II. OUABAIN IN FLINT GLASS CONTAINERS.

Age of Solution	Solvent	Drug Strength	Container	Cat Assay	Guinea Pig Assay	Frog Assay
2 days	95% Alc.	1:1000	Flask	.0788	.00000025	.00000045
*22 months	Water	1:1000	Flint Bottle00000036	.00000067
*32 months	Water	1:1000	Flint Bottle00000055	.00000075
36 months	95% Alc.	1:1000	Flint Bottle00000052

*First and second assays on same sample.

From these tests, it seems that the nature of the container and the presence of alcohol influence the rate of deterioration. While an aqueous solution in an amber cork-stoppered bottle suffers little or no change in strength during twenty-eight months; an aqueous solution in a flint glass-stoppered bottle loses strength to a considerable degree in twenty-two months. Of course, too much weight should not be given the results obtained with such a limited number of samples.

Since the aqueous solutions of Ouabain in amber bottles show no loss in strength that could be detected in twenty-eight months, it seemed unnecessary at this time to test those containing alcohol, because other things being equal, an aqueous solution is preferable to an alcoholic solution for intramuscular or intravenous use. Frog assays with these solutions showed that those containing five percent and ten percent alcohol gave the same value at the end of fourteen months as did the aqueous solutions, the containers being amber bottles.

In conclusion it may be said that the results of our work indicate that aqueous solutions of Ouabain in amber glass containers are sufficiently stable to justify reliance being placed upon them by the physician.

DEPARTMENT OF EXPERIMENTAL MEDICINE, ELI LILLY & Co., Indianapolis, Ind.

THE MEDULLARY RAY CELLS IN RHAMNUS PURSHIANA AND IN RHAMNUS CALIFORNICA.

OLIVER A. FARWELL, DETROIT, MICH.

Ever since *Cascara Sagrada*, *Rhamnus Purshiana*, D. C., became a prominent therapeutic agent it has generally been conceded that it could be distinguished from its near ally, *Rhamnus Californica*, Esch. by the character of its medullary rays as seen in a cross section of the bark. Prof. Henry Kraemer, in a study of the bark of *Rhamnus Purshiana*, (*Journal of the American Pharmaceutical Association*, Vol. 1, page 846, August, 1912) makes the following statement: "It is usual to attempt to differentiate between the barks of *Rhamnus Purshianus* and *Rhamnus Californicus* by reason of the apparent difference in the number of cells comprising the width of the medullary rays." This has reference to the ray as seen in the cross section of the bark. It is possible that most authors, in the study of this work, have relied chiefly upon the number of cells in the width of the ray to distinguish it from *R. Californica*; but it is not the chief character. The two barks can readily be distinguished in cross section by comparing the rays without reference to the number of cells in their width, although those of *R. Purshiana* generally have fewer cells. The rays of *R. Californica* are fewer, probably not over one-half or two-thirds as many and, therefore, have much wider spaces between them; they are more curved and irregularly grouped, and as the ends are not even with the rest of the tissues, as they are in *R. Purshiana*, the cambium edge of the section presents a very pronouncedly wavy or lobed line, that of *R. Purshiana* being even. Prof. Kraemer also calls attention to the fact, which most investigators have either forgotten or overlooked, that the tangential-longitudinal section alone gives the general outline as to height and width of the medullary ray and lays great stress upon the importance of this section, which should be in the cambium region, in furnishing the distinguishing characters in the medullary ray, if such there be, between closely related species. *Rhamnus Purshiana* is illustrated showing the bark in all three sections, cross, radial-, and tangential-longitudinal; *Rhamnus Californica* is not illustrated as Prof. Kraemer did not have authentic material for investigation. Upon reading Prof. Kraemer's paper, I immediately took steps to obtain authentic bark of *Rhamnus Californica* for investigation. A supply was obtained in the fall of 1912 but as no fruit or leaves from the same shrub accompanied the bark, for its identification botanically, nothing was done with it. In the spring of the present year, the collector was again approached, and this time he furnished another supply of the bark, together with flowering branches from the same shrub that furnished the bark. This proved to be typical *Rhamnus Californica* and a comparison of the twig bark with that of the bark in bulk showed the two to be of the same species. In the cross sections of the barks the rays of both species, in the sections examined by me, were from one to four cells wide but in *Rhamnus Purshiana* those of one and two cells in width were quite frequent while they were rare in *Rhamnus Californica*. As to the character of the rays, themselves, which is more important than the number of cells, the dis-

tinctions as outlined above were seen to be well defined. In the tangential-longitudinal section I found the ray in *Rhamnus Purshiana* to be from one to five cells in width, commonly three or four; in *Rhamnus Californica* the ray in from one to seven cells wide, commonly four or five. In the former the cells are pretty evenly arranged in lines, and are of about the same size; while in the latter, when more than four cells wide, the cells are irregularly arranged in the center of the ray and of variable size.

Perhaps it will not be amiss before dismissing the subject to make a few remarks upon the cultivation of *Rhamnus Purshiana* in Michigan. The plant, according to the *Kew Bulletin*, has been, for several years, cultivated with success in Ireland. In 1907, at my request, Messrs. Parke, Davis & Co. procured about eighty seedlings of *Rhamnus Purshiana* from Oregon. These were transplanted in October of that year on the lawn in front of the laboratory. The trees are not protected with winter buds so it was a question as to whether or not they would withstand the rigor of our climate. In order to make a thorough test they were planted near the Detroit river and ran inland or in a line at right angles with the river bank. Most of them would be directly exposed to the freezing winds from the icy river while a few would be more or less protected by near-by buildings. The first winter the transplanted seedlings were well protected by wrappings of straw and sacks while the ground was covered with plenty of straw; in the following winters they were not protected. During the six years since they were planted about eighty-five percent have died or all that were not protected from the cold winds from the river. The more vigorous trees are about 12 feet in height and 4 inches in diameter at the ground. They have blossomed this year for the first time but no fruit has developed. The plants were planted in made ground consisting mostly of blue clay and some greyish clayey loam. The inference is that *Rhamnus Purshiana* can be successfully cultivated in Michigan in situations where it can be protected from the direct blasts of the cold icy winds.

BOTANICAL LABORATORY OF PARKE, DAVIS & Co., Detroit, Mich.

NOTE ON THE ACIDITY OF HYDROGEN PEROXIDE SOLUTION.

B. L. MURRAY, PH. C., RAHWAY, N. J.

The acidity of solutions of hydrogen peroxide may be due to one or more acids, free phosphoric, sulphuric, or hydrochloric acid usually being present. To determine quantitatively how much free acid is present has been studied by many, and with varying success. The choice of an indicator for the titration must be made, and it has generally been attempted to select one indicator suitable for all cases. Of course the amount of free acid in solution of hydrogen peroxide for general medicinal use does not need to be controlled very closely, so perhaps one indicator for all acids is sufficient. But by following out a suggestion published

by the writer some years ago, and lately elaborated, we can easily select an indicator suitable to the acid to be titrated.

It was advised that one could decompose the hydrogen peroxide by means of platinum metal, subsequently titrating the acid remaining. This procedure has now assumed this shape. Place the customary 25 cc. sample of peroxide and an excess of decinormal solution of sodium hydroxide in a long test tube (about 8 or 10 inches long). Add about three grams of platinized pumice stone and place the tube in a steam bath for about 15 minutes, or until the peroxide is all decomposed. The heat and the shape of the container (long and narrow) hasten the reaction. It only remains to pour the remaining liquid into a beaker or flask and complete the titration of the acid that was in the peroxide, now in simple aqueous solution as a sodium salt. In our hands an excess of standardized acid is generally added, followed by boiling and subsequent titration with decinormal alkali. Any indicator suitable to the acid and conditions at hand can be used. Experiments show that it is easy by the above method to so completely destroy the peroxide that no reduction of permanganate can be obtained from the resulting liquid. The pumice stone is easily prepared by soaking the stone in solution of platinic chloride, then igniting, then re-soaking and re-igniting. It is used over and over.

THE EDUCATION OF THE PUBLIC.

The education of the public in matters pharmaceutical is being attempted in various states, with the object of putting the druggist right in the eyes of the public. During the past decade certain lay newspapers have carried on campaigns against the proprietary medicine business, with the admitted object of destroying it. Recently there appeared in the "Ladies' Home Journal" an article entitled "The Meanest Business in the World—Cheating the Sick," wherein remedies for women's ailments, soothing-syrups, and headache and cough preparations were condemned as a class. Unfortunately, the writer made his attack too inclusive, stating that such medicines (excluding the first named) "all depend for their effect upon alcohol, and one or all of the stupefying drugs—opium, morphine, or chloroform." The writer went on to say that "used to excess they kill outright; used even in moderation, they gradually become a necessity to the child's system, and before the parents realize the danger they have on their hands a victim of the drug habit." Such misstatements are freely copied by the newspapers throughout the country, with the result that an unmerited slur is cast upon the drug business. In order to combat this influence, the Wisconsin State Pharmaceutical Association has formed a publicity bureau, charged with the duty of disseminating among the country papers short articles that will set the druggist right in the public eye. The time has come when the public must be told that the maker of ready-made medicine is not necessarily a faker and a charlatan.—American Letter in *The Chemist and Druggist* (London).

Papers Presented at the Sixty-First Annual Convention

PHARMACOPŒIAL TITLES FOR NEW REMEDIES.

M. I. WILBERT, WASHINGTON, D. C.

A review of the now existing national pharmacopœias suggests the thought that from the point of view of nomenclature the several books may be classified as following either the English, French, Scandinavian or German system and that apart from adhering more or less closely to the general style that has been in the prototype, little or no attempt has as yet been made to secure any degree of international uniformity in the accepted title for official articles.

The greatest amount of variation is of course to be found in connection with the official names for chemical substances, and using these names as the basis for the classification, we find that broadly speaking, the English style is followed only in the British Pharmacopœia and in the Pharmacopœia of the United States. The French system gives precedence to the vernacular title and uses the Latin only as a secondary title, usually for chemical substances and galencial preparations that are prescribed by physicians. Vernacular titles occur in the French, Spanish and Italian Pharmacopœias. The Scandinavian style, which it may be here pointed out, is based on an understanding between representatives of the Scandinavian countries, still adheres closely to the Berzelian system of nomenclature, giving precedence to the acidic radical in salts. This system is followed rather closely in the Swedish, Norwegian, Danish and Dutch Pharmacopœias, in the Latin titles of the Spanish and Italian Pharmacopœias and in the Latin synonyms of the Belgian Pharmacopœia. The German system so well known to us through the German Pharmacopœia is also included in the Swiss, Russian, Belgian, Austrian, Hungarian, Servian and Japanese Pharmacopœias, in the Latin titles of the French Pharmacopœia and the synonyms of the Danish Pharmacopœia.

The possible mistaking of the name for a comparatively innocuous substance for that of a much more active one has been repeatedly cited as an argument for greater uniformity. In this connection it will suffice to call attention to the Continental "chloratum," which in English speaking countries has not infrequently been mistaken for chlorate in place of chloride.

The exceptional titles for widely used chemical substances occur almost exclusively in the American and the British Pharmacopœias, which have uniformly adopted potassium and sodium for the universally used kalium and natrium despite the fact that kalium and natrium are thoroughly well established as designations for the elements themselves in connection with the symbols for atomic

weights. A somewhat similar exception occurs in the Russian Pharmacopœia where "magnium" is used in place of magnesium.

The obstacles in the way of international uniformity in pharmacopœial nomenclature are not so many and so varied as one would expect from the truly provincial system of pharmacopœial revision that has generally prevailed up to recent years. With a modernization of the pharmacopœias still adhering to the Berzelian system of nomenclature and sundry slight changes on the part of the Pharmacopœias of the United States and of Great Britain, the nomenclature of chemical substances, of pharmacopœial preparations and of practically all drugs could be readily made uniform and even at the present time this uniformity could be obtained for all practical purposes if the revisers of these several pharmacopœias would adopt the precedent established by the Committee of Revision of the Danish Pharmacopœia and include the most widely used official titles as synonyms.

A rather more difficult problem is, however, presented by the official recognition of some of the newer chemical remedies, particularly those of foreign manufacture which have been given short and catchy titles by the manufacturers. These titles, in some countries, at least, are accepted as property and protected by law, while in other countries, our own for example, where the law does not provide for such protection, the general adoption of the names has been prevented by fear of legal difficulties.

Some idea of the complications existing at the present time may be gathered from the following enumeration of the titles under which three widely used articles have been included in foreign pharmacopœias:

Theobromine Sodium Salicylate—

Theobrominum Natrio-salicylicum, Austr., Belg., Japan.

Theobromino-Natrium salicylicum, Germ., Helv.

Salicylas natrico-theobromicus, Dan.

Salicylas natricum cum Theobromino-Natrio, Ndl.

Salicylas sodæ et theobrominæ, Hisp.

Theobromino-salicylas natricus, Svec.

Diuretin (as a synonym), Austr., Belg., Dan., Svec., Ital., Hisp.

Epinephrine—

Adrenalinum, Fr., Helv., Ital., Belg.

Suprarenin hydrochloricum, Germ.

Suprareninum, Ndl. (Suppl.)

Aspirin—

Acidum acetylosalicylicum, Helv., Germ.

Acidum acetylo-salicylicum, Dan.

Acidum Acetylsalicylicum, Fr.

Acidum acetsalicylicum, Japan.

Aspirin, As a synonym in Germ.

In the U. S. P. VIII an attempt was made to include some of the newer remedies under abbreviated titles. The following list gives the titles under which several of these articles have been included in our own and in foreign pharma-

copœias and it is rather interesting to note that with the single exception of acetphenetidin, not any of the abbreviated names have as yet found favor with other pharmacopœial revisers:

Acetphenetidinum—

Phenacetinum, Germ., Brit., Ndl., Japan., Belg., Dan., Helv., Svec., Hung., Fr., Russ., and as a synonym in Austr., Serb.

Fenacetina, Hisp., Ital.

Acetphenetidinum, Austr., Serb.

Hexamethylenamina—

Hexamethylenetetraminum, Germ., Ndl., Japan., Dan., Helv., Svec., Ital.

Utropin (as a synonym), Germ., Ndl., Dan., Ital.

Sulphonethylmethanum—

Trionalum, Austr., Svec., Fr., Ital., Hung., and as a synonym in Ndl. and Belg.

Methylsulfonalum, Germ., Ndl., Belg.

Methyl Sulfonalum, Japan.

Sulphonmethanum—

Sulfonalum, Germ., Hisp., Ndl., Japan., Belg., Austr., Dan., Helv., Svec., Fr., Serb., Ital., Hung., Russ.

Sulphonal, Brit.

A rather significant indication of the lack of popularity that has been developed by these abbreviated titles is suggested by a review of the Index Medicus for the years 1905-1912, inclusive. This publication, as is well known, reflects in a rather comprehensive way the medical literature of the world and a careful search through the index of the publication fails to show a single occurrence of the words acetphenetidin, sulphonethylmethane and sulphonmethane, despite the fact that phenacetin, trional and sulphonal occur repeatedly. Urotropin and some of the other proprietary names for hexamethylenetetramine also occur in all of the several volumes, though hexamethylene does not occur at all in the volumes previous to 1908. In the latter year, owing no doubt to the inclusion of the drug as hexamethylenetetramine in a number of European pharmacopœias, the name occurs in connection with the title for one paper and re-occurs in several succeeding years, but very sparingly.

The ointment bases of the Pharmacopœia appear to offer rather a difficult problem from the American point of view, largely perhaps because of the fact that succeeding committees of revision have been unwilling to undertake a possible legal controversy in regard to proprietorship in name. Designed as our laws are to protect the interests of the many against the usurpations of the few, it would appear to be a comparatively simple procedure to have the legal rights of the people at large adequately defined either by statute or by court decisions. Trade-mark registration in this country involves no recognition of property right and is at best but a record of claim to ownership. The present law obviously restricts the right of ownership in a trade-mark to a designation of the brand of a particular product made by a manufacturer and this mark or designation must be apart from the title under which the article is known or sold. The following names for widely used ointment bases illustrate the difficulties that have

been encountered with the problems abroad and also suggest the desirability of proper inquiry as to the validity of existing trade-marks in this country.

Adeps Lanæ Hydrosus—

Adeps lanæ cum aqua—Germ. IV, Ndl., Japan., Dan., Russ., Fr., and as a synonym in Belg., Helv.

Lanolinum—Helv., Svec., Germ. V, Ital., and as a synonym in Ndl., Austr., and Dan.

Adeps lanæ hydrosus—Brit., Austr., Serb., Hung.

Lanolinum cum aqua—Belg.

Petrolatum—

Vaselinum—Japan., Belg., Austr., Dan., Helv., Svec., Fr., Serv., Ital., Russ.

Vaselinum flavum p., Germ. V, Ndl., Hung.

Paraffinum molle—Brit.

Vaselina—Hisp.

The U. S. P. title "*Adeps Lanæ Hydrosus*" has never come into general use and as a court decision (Hyg. Lab. Bull. No. 87, p. 205) has long since established the fact that the name lanolin became a free title when the patent on the product expired there appears to be no reason why anhydrous lanolin and lanolin should not be used in place of wool fat and hydrated wool fat in the Pharmacopœia of the United States.

The word "Vaselin" is so widely used as a popular title for a semi-solid fatty substance obtained from petroleum, and in European countries particularly has been so uniformly accepted as the official name for the product included in our own Pharmacopœia as petrolatum that there is considerable reason for the use of the word "vaselin" regardless of the claim that it is or was used as a trade-mark for the product of any one firm.

The U. S. P. title for one of the comparatively new remedies, "Solution of Hydrogen Dioxide," has been severely criticized, by chemists particularly, who point out that dioxide is used to designate certain definite combinations like manganese dioxide and is not applicable to a peroxide such as exists in the official solution. There appears to be no well founded reason why our official title should not comply with foreign pharmacopœias, and it might well be made to read "Solution of Hydrogen Peroxide."

As noted above, the problems involved in the securing of international uniformity in pharmacopœial titles while at times complicated, are by no means insurmountable and could be readily overcome if the revisers of the several pharmacopœias made sincere and consistent efforts to do so.

DISCUSSION.

W. C. Alpers, of New York, said Mr. Wilbert had expressed the wish in his paper to avoid the mistake made in foreign pharmacopœias of including the synonyms of an entire nation in the pharmacopœia. There was a tendency among some people to expect everything of the pharmacopœia. They thought the pharmacopœia was a pharmaceutical cyclopedia. He had always opposed this idea. He did not believe a pharmacopœia should be anything else than a book of standards for the drugs and chemicals used in the country for which it was intended. The question of bringing harmony out of the chaos of different nomenclatures rested with the International Pharmaceutical Congress, and one of the objects of that Congress was to find a way of uniformity in this matter, but it would probably be many years

before this desired end was accomplished. He had no doubt the same desire existed in other countries as in this, of bringing about greater uniformity. But, in the very nature of things, care must be exercised in a matter of this kind, and progress would necessarily be slow. No committee that could be appointed could successfully deal with a subject of such broad scope, and the only thing that could be done was to make recommendations to the International Congress as to this particular phase of their work; but not until the pharmacists of the world were gotten near enough together, by a conference, on scientific matters, would a remedy be found.

Mr. Wilbert responded that the pharmacists of America were extremely slow to adopt the recommendations of the International Congress. The Brussels Conference had suggested, not one name, but several for each article, and in a number of instances none of these had been adopted in this country. The International Conference could only suggest or recommend, and true uniformity could be had only when the necessity of such a thing became apparent everywhere. The trouble with the pharmacists of America was, that they were so provincial they were not willing to adopt the recommendations made by the International Congress, and put in the form of an international treaty signed by diplomatic representatives. This was one serious fault of the pharmacists of this country, they were over-conservative in making headway in such directions as this.

James M. Good, of St. Louis, thought it could be only pure selfishness that would deny the privilege of using the name "phenacetin." What one of the speakers had said did not apply with the same force to phenacetin that it did to diuretin, for instance. In many drug stores, it was not known that acetphenetidin was the official name for what was the proprietary product "phenacetin." He thought there was no necessity for the two names. Out in St. Louis, he said, a man could say, "I want to be called 'George Washington,'" and the courts would allow him to adopt the name; but it was a different proposition when it came to the United States courts. "Why, are we afraid of these people," he asked, "and hence not willing to give these synonyms?" He understood from what Mr. Raubenheimer had said that the probabilities were, that these people did not want any legal facts to be in the hands of the pharmacists of the country.

Mr. Wilbert, commenting upon this last suggestion, as to the legal phase of this matter, said that the American Medical Association, which was a responsible financial institution, had said that these names were applicable to the pharmacopœial articles. These facts had been published in the Journal of the American Medical Association repeatedly, and if these people had desired to do any fighting they had had ample opportunity.

Mr. Good suggested that it might be put up to the Pharmacopœial Committee as to whether or not these synonyms could be used. This was a subject that all pharmacists were vitally interested in, and he thought this Committee of Fifty could deal with it. Very few pharmacists were capable of acting intelligently on a proposition of this kind, but the committee should be able to give a good reason for whatever it did.

TABELLÆ DULCES, SWEET TABLETS FOR CHILDREN'S MEDICATION.

BERNARD FANTUS, M. D., PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS,
COLLEGE OF MEDICINE OF THE UNIVERSITY OF ILLINOIS, CHICAGO.

Modern pharmacy boasts of many elegant and palatable preparations suitable for adults. But very little has thus far been done in this line for children, and yet attractiveness and palatability are even more important for the little ones than for the grown-up. Syrups have hitherto been our chief aids in making medicines more acceptable to children. Unfortunately, many a child has had its palate

offended by liquid medicine so that it abhors spoon-medicine of any kind, and will struggle even against the most palatable. It is especially for such children—and there are a great many of these—that another method of administration is needed. As all children love candy, this form would seem to be most desirable for children.

In name and in principle, "candy medication" is even now recognized by the Pharmacopœia. Have we not confections and troches? Unfortunately, the pharmacopœial conception of a confection does not coincide with the confectioner's. Have you ever seen Confection of Rose sold in a candy store? If it were a really delicious confection would not the confectioner be glad to take it up? Confection of Senna is far from being delicious. I know whereof I speak. In the early days of my experiments on "candy medication," I tried to put Confection of Senna into attractive dosage forms with the hope of making the youngsters think it was candy; but without the least success. Troches have been defined as "confections made into various dosage forms and dried." How many troches are real candy? How many of them are popular? Of course, I recognize that the chief purpose of troches is throat medication and not palatability; that they are intended to dissolve slowly in the mouth, so as to give prolonged contact of the medicament with the throat. Real "candy medication" is therefore not yet to be found in the Pharmacopœia.

The sweet tablets to which I desire to call your attention are—to use a phrase of the drug-store vernacular—"just as good as" candy; and they are the only candy form I know of that can be prepared extemporaneously by the pharmacist. These tablets, to be successful, must be perfectly pleasant, actually delicious sweets, free from any suggestion of medicinal taste or odor, as the ailing child is liable to be very critical. The tablet should disintegrate readily in the mouth, for a sick child usually will not chew or suck candy as a healthy one would.

Having conducted a study to determine to what extent the materia medica would lend itself to this form of medication, I was surprised to find that the list was quite extensive. Within the last few weeks I have been able to enlarge this list still further, thanks to the discovery by John Uri Lloyd, of almost tasteless compounds of the alkaloids, called by him Alcresta Alkaloids, which are obtained by precipitating alkaloidal salts with a reagent that, I am told, is essentially composed of hydrous aluminum silicate which combines with alkaloids possibly by reason of adsorption. These precipitates are insoluble in neutral and in acid liquids but soluble in alkaline fluids; hence may be expected to unfold their activity in the intestine. The slight alkalinity of the saliva does not liberate enough of the alkaloid to bring out the bitterness excepting in case of the strychnine and of the quinine compounds. These Lloyd has subdued practically to tastelessness by combining the strychnine with free tartaric acid, and in case of quinine by combining it with glycyrrhiza and a tannin. The first question that comes to one's mind is, whether by removing the taste, the activity is not likewise annulled. That this is not the case can be positively asserted in regard to strychnine, the Alcresta compound of which will kill a dog quite as readily as strychnine sulphate. It may be inferred that the other preparations will likewise not be impaired in their activity; though this remains to be demonstrated. By the use of these compounds, the alkaloids become available for administration

in candy form. Strychnine can be given to the extent of 1/200 grain per 5 grain chocolate tablet. The Alcresta compounds of morphine, of codeine, of cocaine, and of atropine, permit the administration of adult doses in five grain sweet tablets. I have also experimented with Alcresta compounds of cinchonine, cinchonidine, berberine, sanguinarine, gelsemium alkaloids; and have found all of them more or less suitable for this method of administration. It is evident therefore that sweet tablets are a form of pleasant administration of such wide applicability that it would rarely be necessary to inflict upon children less pleasant medicine.

I have found three fundamentally different formulæ of use: 1, Sugar tablets; 2, Chocolate tablets; 3, Licorice tablets.

1. *Sugar Tablets*.—There are quite a number of medicines sufficiently free from taste to be made pleasant by the mere admixture of sugar and of flavoring. The addition of a little of harmless coloring seems desirable, as pleasing color adds considerably to the attractiveness of the tablet for the little ones. The powder, after having been moistened with alcohol, may be moulded in a tablet triturate mould. Or else, it may be made into compressed tablets by the use of an inexpensive tablet machine. The addition to the powder of 3 percent of cacao butter or of paraffin causes it to retain the shape imparted to it by the machine; the paraffin being preferable if the tablet is to be kept for some time; cacao butter, if it is for immediate consumption. If the powder has a tendency to stick to the dies, the further addition of 3 percent talcum is advantageous. If a considerable amount of insoluble powder enters into the composition of the tablet, the addition of talcum is unnecessary. The following might be taken as a typical formula for sugar tablet:

TABELLAE TERPINI HYDRATIS DULCES, GR. ½.

SWEET TABLETS OF TERPIN HYDRATE.

Terpin hydrate	50 grains
Paraffin, low melting point, in thin shavings.....	15 grains
Tincture of curcuma.....	60 minims
Spirit of rose, 10%.....	5 minims
Powdered sugar	435 grains

Mix the terpin hydrate with the sugar, the coloring and the flavoring by thorough trituration in a mortar, incorporate the paraffin by gentle trituration; and compress in tablet machine, using three-eighths-inch die and punches, to make 100 five-grain tablets.

It might be remarked in passing that these tablets of terpin hydrate, as well as quite a number of others, are not only suitable for children's medication, but for adults as well. Two of these tablets would be equivalent to a teaspoonful of the N. F. Elixir of Terpin Hydrate in a much more pleasant form.

2. *Chocolate Tablets*.—Substances that have a slightly bitter or otherwise slightly disagreeable taste can well be disguised by the addition of 10 to 20 percent of powdered cacao to the sugar. The addition of a small amount of Tincture of Vanilla, say 3 percent, is of advantage to improve the flavor of the cacao. So nicely does the cacao-containing powder lend itself to compression in a tablet machine, that the formula for the chocolate tablet might be considered the formula

of choice, if one general formula for sweet tablets were desired. The following might serve as a typical example:

TABELLAE ACETPHENETIDINI DULCES, GR. $\frac{1}{2}$.

SWEET TABLETS OF ACETPHENETIDIN.

Acetphenetidin	50 grains
Powdered cacao	100 grains
Tincture of vanilla.....	15 minims
Powdered sugar	350 grains

Mix the ingredients by thorough trituration in a mortar; and compress in tablet machine, using three-eighths-inch die and punches, to make 100 five-grain tablets.

The taste of tablets containing some of the ordinary salts of alkaloids can be improved by the addition of a small amount (1%) of sodium bicarbonate; some need a little saccharin in addition. To the Alcresta alkaloids, on the other hand, alkali must not be added, as that would bring out the bitterness.

3. *Licorice Tablets*.—There are a few substances that are better disguised by extract of glycyrrhiza than by cacao. A formula for such a tablet would be:

TABELLAE ANTIPYRINAE DULCES, GR. $\frac{1}{2}$.

SWEET TABLETS OF ANTIPYRIN.

Antipyrin	50 grains
Extract of glycyrrhiza, powdered.....	25 grains
Caramel, 50% solution.....	30 minims
Spirit of anise, 10%.....	8 minims
Spirit of coriander, 10%.....	4 minims
Powdered sugar	425 grains

Mix the ingredients by through trituration in a mortar; and compress in tablet machine, using three-eighths-inch die and punches, to make 100 five-grain tablets.

These sweet tablets are so delightful in practice among children, that any one who has used them once would never again wish to do without them. Why should iron ever be given to a child in other form than that of some delicious sweet tablets of iron carbonate? Why should a little one suffering from cardiac weakness and in need of a heart tonic be permitted to struggle against medicine, and thereby jeopardize its life, when digitalin, strophanthin and even strychnine can be given in candy form? And quinine can be given in positively pleasant form as sweet tablets of aristochin, of saloquinine, or of Alcresta quinine.

If these sweet tablets are useful in medical practice—and it can readily be proved that some of them are—why should not one of our formularies, the Pharmacopœia or the National Formulary, help in introducing them? Why should not the pharmacists of the country be given the opportunity of preparing these tablets? There is no doubt in my mind that any pharmacist who will equip himself with the necessary apparatus, costing not much more than \$10, and who will busy himself to get the physicians of his district acquainted with these new preparations, would reap a rich harvest. Should pharmacists equip themselves to prepare these tablets extemporaneously so that physicians could prescribe them, the patient would receive a fresh product fitted exactly to his needs, for

the dose could be modified and several medicaments combined in the same tablet, as occasion may require.

My conclusions are:

1. There are a considerable number of drugs that can be administered in form of perfectly sweet tablets, particularly desirable for children's medication.
2. These sweet tablets can be readily prepared extemporaneously by any pharmacist equipped with an inexpensive apparatus.
3. A few sweet tablets, such as those of calomel and of phenolphthalein are now in extensive use.
4. These and a few others of undoubted desirability should be introduced into the Pharmacopœia or the National Formulary.
5. If this be done, a definite advance in pharmacy would be recorded, suffering childhood would many times be spared the hardship of having nasty medicine forced upon it, and grateful mothers and nurses would bless the day of the new medication.

DISCUSSION.

Mr. Wm. C. Alpers, calling attention to the use of the three colors, green, red and white, obtained by solutions of malachite green and carmine, and tincture of curcuma, respectively, suggested that green might more appropriately be applied to tablets that should be classified as poisons,—to drugs like arsenic, and antimony-potassium tartrate,—and expressed the opinion that some system should be observed in the coloring scheme. Comparing the two formulas for terpin hydrate and terpin hydrate with heroin, he pointed out the difference between the two, in that, with the latter, chocolate powder was used as the coloring-matter, whereas with the first-named tincture of curcuma was used. Again, as to flavors, the one was flavored with vanilla, while the other was flavored with spirit of rose. If any system was employed, he desired to be enlightened upon that point. He suggested that one would naturally think, as to these two formulas, that they would be in the same system. He thought it might be a question as to whether sugar should be used in all cases for children; but this was not a question for the pharmacist, but for the physician himself to answer.

Doctor Fantus said he appreciated the remarks of Doctor Alpers, and that there was a certain amount of system observed in the coloring scheme he had used. He had tried to use green or deep red for poisonous substances. For instance, there was elaterin, a substance that might be considered rather active. He had used as deep a red for that as he thought desirable. Then, there was hyoscine, which was colored a rather deep red. And again, green was used for some poisonous tablets. He confessed that he had not carried out this idea as consistently as might be desirable. He had found green was attractive to children, and he had also used it for other tablets, that were not poisonous for instance with acetylamidosalol. The idea advanced of marking poisons by a particular color seemed to him to be a good one, and it would be carried out more definitely in future work.

The difference in color between terpin hydrate tablets and those of terpin hydrate with heroin, was due to the bitterness of the heroin, which was best disguised by chocolate. He called attention to the fact that the heroin tablets were also chocolate tablets.

As to the question whether sugar might not be, at times, objectionable in the treatment of sick children, he confessed that it had also given him considerable concern. However, the conditions in which the small amount of sugar given with the medicaments in this form would be objectionable must be very rare indeed.

These tablets were not intended for babies. They were intended for children, from the ages of three years to nine; and the doses were calculated for a child of three, although some of them could be given in larger doses. Children of that size he did not believe would be harmed by the amount of sugar given them in connection with the remedy. Anyhow, actual experience with many of these had shown that was not the case.

This work was merely experimental, and more to show how many different medicaments

could be put up in this form. Some of them would probably be useless. Experience would show how many could be successfully used. He had found his own practice to increase to a marked degree since he had been using this form of medication.

Dr. Fantus concluded by saying that he had brought this subject before this body of representative pharmacists of the country for the reason that he wished their coöperation in keeping this form of medication in the hands of legitimate pharmaceutical practice, instead of having it forced upon the market as a new line of proprietary medicines.

W. R. White, of Nashville, said he was particularly interested and pleased with this paper. It bore on a subject that he had given some attention to heretofore, in a paper that he had read before the Los Angeles meeting, in which the subject of chocolate and its uses in pharmacy were considered. In that paper he had referred to the use of chocolate in disguising the taste of a great many different medicines. One question that presented itself to his mind and which was not brought out here was the fact that some people did not swallow tablets, and in such cases a powder was necessary to be administered. In these cases he thought a powder consisting of chocolate and sugar might be prepared and used in many instances, instead of the aromatic and other powders used. The value of chocolate was being more and more recognized, continually. A good many pharmaceutical houses were using it in preparations that were elegant, and they had become very popular.

J. L. Lascoff, of New York, called attention to the fact that Doctor Fantus had said that there were certain manufacturers putting on the market strychnine and other poisonous substances in tablet form, and stated that several cases of poisoning had occurred with children, where they had mistaken these tablets for candy. He thought all poison tablets should be of a certain color, for distinction. For instance, terpin hydrate tablets should be of a distinctive color. He said he had found a tablet machine costing \$30.00 to give good results.

F. E. Stewart, of Philadelphia, said that he was very much interested in this subject when Doctor Fantus presented it to the meeting of the American Medical Association. He feared, however, that if the idea was logically carried out it would ruin the pharmaceutical business. He thought pharmacists were doing all they could to put themselves out of business by encouraging such things as this, and expressed the opinion that, if this kind of medication became very popular, it would be a question as to whether the pharmacist would have anything to do.

W. C. Alpers, speaking again on this subject, thought that if these tablets should become popular there was no doubt but that the manufacturing houses would make them; that they would not be made in the store of the pharmacist, but every manufacturer would take advantage of the opportunity, and offer them for sale. He thought it would be manifestly desirable in such case that tablets of the same kind should be turned out of the same color by the different houses, and right at the beginning the inventor should lay down certain rules as to the coloring. He could foresee that the failure to do this would lead to all sorts of trouble. The patient buying a tablet of a certain kind and color at one store would immediately raise objection if he was offered the same thing at another store in a different color. He thought that this question should be well-considered and determined by creating right at the start a well-defined system as to color. He was decidedly of the opinion that one distinctive color should be adopted for poisons; the rest could then be arranged in other ways. This would not apply to those articles where chocolate was used for the outside coating, but the rest should have a definite color-scheme. By following out this idea, a great deal of confusion, which would inevitably arise otherwise, would be avoided.

Continuing, Mr. Alpers called attention to the fact that a chocolate quinine tablet was being sold on the market, and suggested that a quinine tannate was formed from the tannin in the chocolate, which, being insoluble, had no taste. He said a great many physicians would not allow their patients to use these quinine chocolate tablets because of this insolubility, which they regarded as making them worthless. According to them, the presence of chocolate in the quinine tablets would make them objectionable.

Otto Raubenheimer, of Brooklyn, said that all knew how hard it was to administer medicine to children. Doctor Fantus had certainly taken a step in the right direction, in originating a scheme of preparing tablets which was intended for the pharmacist, and not for the

manufacturer. Of course, if the pharmacist remained ignorant and lazy, and did not prepare these tablets, the manufacturer would do it. These tablets could be made by the pharmacist by an inexpensive machine, and he had something here that he could make some money out of.

He did not agree that there was tannin in chocolate. The quinine chocolate tablets were prepared with quinine tannate. He thanked Doctor Fantus for originating these tablets, and expressed the hope that some standard work like the Pharmacopœia or the National Formulary would take up some of these formulas.

Doctor Fantus thanked the members very heartily for the interest taken in this work, and for the ideas brought forward. He regretted that he was not familiar with the paper referred to by Mr. White, in regard to the use of chocolate in disguising the taste of medicine, as he should have given him credit if he had known of it. It should be understood that these tablets should always be dissolved in the mouth; they were not intended to be swallowed whole. He saw no reasons for tablet-making, excepting for the purpose of either hypodermic administration or to be dissolved in the mouth. A pill could be swallowed much more readily than a tablet. A tablet was made in imitation of candy, and that was the reason it was attractive to children. He had found that powders were of no advantage, because children rebelled against them.

He admitted that the possibility of poisoning was probably the most serious objection to candy medication. There was undoubtedly danger that a child might get hold of a quantity of such poisonous tablets and eat them. However, that danger could be readily overcome by not prescribing, and not permitting to come into the house, any more than could be safely taken at one dose. Thus, if the physician prescribed only a few morphine tablets, and the little patient got hold of them and ate them all, no harm would be done. And the same with aconitine, and so on.

Referring to Mr. Alpers' suggestion that he should systematize a color-scheme for these tablets, Dr. Fantus agreed that this was an excellent idea, and he would profit by it.

A tablet machine, that would satisfactorily turn out prescription quantities of tablets, could be obtained from Whitall, Tatum & Co. at about \$10.00. Doctor Fantus could see no reason why pharmacists should not take up tablet making.

F. W. Nitardy, of Denver, said that, some years ago, he had experimented with putting up castor oil in the form of candy, and had met with fair success. He had not done much with it of late, however. He put up the castor oil in the form of chocolate creams, each containing a teaspoonful of castor oil; and they were sufficiently disguised to deceive the clerks in the store to whom he handed around these creams; at least, none of them found out it was castor oil or that the candy was medicated, until they had been told. The process consisted of making an emulsion of castor oil, with condensed milk, sugar and flavoring, so that the finished product was of proper consistence and contained 50% castor oil. This was divided into lumps of about $\frac{3}{4}$ oz. each, which were then dipped in chocolate.

Doctor Fantus said he had worked with chocolate creams himself, but his experiments with cod liver oil in this form had been a failure—although in his early studies in this form of medication he had taken the pains to go to a candymaker for instruction, that he might find out what forms of candy would be most suitable for various forms of medication. He was not the first, however, to use chocolate cream in medication. Sir James Sawyer had published a process in *The Lancet* in 1911 for making medicinal chocolate creams, for which he had proposed the name "Cremulæ."

In response to a question by Mr. Lascoff, Doctor Fantus said that any process that required drying was practically excluded from extemporaneous pharmacy, for this reason, lozenges were excluded. The granulation ordinarily prepared for tablet making also required drying. A. Schleimer suggested, in 1909, the use of cacao tablet making. Three percent of cacao butter would do, but some tablets made with it would not keep well. He had endeavored to find some substance to substitute for cacao butter, and found that paraffin did just as well, using the same percentage. There might be some objection to paraffin, as it was insoluble and indigestible. He thought cacao butter should be preferred for tablets that are not to be kept for any length of time.

Section on Education and Legislation

Papers Presented at the Sixty-First Annual Convention

SOME ASPECTS OF OUR POISON LAWS.

B. L. MURRAY AND A. W. FRAME.

If there is any one here that handles poisons in a commercial way he can doubtless anticipate parts of this paper. For any one that handles poisons must label them and to label them properly is a difficult task. It is not such a troublesome task where the business is confined to one single state, but the uncertainties increase when an interstate business is attempted. In one single state there is generally the state poison law to be complied with, and, in addition, sometimes the city ordinances of some of the larger cities; while in interstate business there are forty or fifty poison laws to be taken into consideration. And yet without undertaking an *exhaustive* criticism of present poison laws, we are here to-day advocating the enactment of still another poison law; a law especially applicable to the interstate traffic in poisons.

The real difficulty in labeling poisons is not exactly in the *wording* of the label. It is easy, as a rule, to decide upon the wording of poison labels, selecting the color of the ink, the proper antidote, etc. The serious part of the work comes in deciding what articles are poisons and what are not. On this feature (deciding what articles are poisons) there seems to be no uniformity of opinion. Wide variations in the individual state laws occur at this point, and one is finally brought to the homely question: What is a poison? The answer to this question is, or at least seems to be: We do not know. Just here is where the trade comes into difficulties. The trade as a whole wants to comply with the laws, but can find nothing substantial in the way of a poison law upon which to stand.

But surely in order to properly classify our various drugs and preparations as poisons or non-poisons, and then to label them, we must inquire as to the meaning of the word "poison." In these days of multi-legislation it becomes essential at once to inquire what the statutes say a poison is. Some definitions or statements that might be interpreted as definitions from state laws follow:

"Any substance which in doses of 5 grains or less is destructive of human life." (New Jersey.)

"Any poisonous medicine fatal to human life in doses of 15 grains or less." (S. D.)

"Any drug, chemical, medicine, or preparation liable to be destructive to adult human life in quantities of 60 grains or less." (N. Y.)

"Any drug, chemical or preparation which, according to standard works on

medicine or materia medica, is liable to be destructive to adult human life in quantities of 60 grains or less." (Kentucky.)

"Any drug, chemical, or preparation which according to the Pharmacopœia and Formulary and Homeopathic Pharmacopœia is destructive to adult human life in quantities of 60 grains or less." (N. Y.)

"All vegetable poisonous drugs and their pharmaceutical preparations and alkaloids." (N. M.)

"Article of a nature poisonous to the human system or to animals." (Louisiana.)

"Any chemical, drug, or medicine which is poisonous or which contains a poison." (Indiana.)

"Any article belonging to the class of medicines usually denominated poisons." (Miss.)

"Any article or articles of medicines belonging to the class usually known as poisons." (Neb.)

"Drugs commonly known as deadly poisons." (Porto Rico.)

"Any dangerously poisonous drug." (Utah.)

"Any deadly poison." (Hawaii.)

Much vagueness and indefiniteness is seen in making a comparison of the above definitions. But note, too, the deplorable lack of uniformity. Upon which of these definitions can one rest and feel sure that he is right, or even reasonably sure? How can any one comply with them? At first thought it would seem that poison in one state would be poison in another state, and thus a uniformity of definition might be expected. But apparently what is poison for mankind in one state is food for mankind in another state.

The conclusions of the courts are reflected in the following:

"A poison is an agent which when introduced into the animal organism, is capable of producing a morbid, noxious or deadly effect upon it."

"Any substance that, when taken into the system, acts in a noxious manner by means not mechanical, tending to cause death or serious detriment to health."

"A substance of definite chemical composition which when taken into the living organism is capable of causing impairment or cessation of function."

"Any substance which when taken into the body and either by being absorbed or by its direct chemical action upon the parts with which it comes in contact or when applied externally and entering into circulation is capable of producing deleterious effects."

Some dictionary definitions of poison are offered. But they do not bring us much nearer to a satisfactory idea of a poison.

"A general name for all substances which, when introduced into the animal economy either by cutaneous absorption, respiration or the digestive canal act in a noxious manner on the vital properties or the textures of an organ."—The Dunglison Medical Dictionary.

"A substance having an inherent deleterious property which renders it when taken into the system capable of destroying life."—Wharton & Stille Medical Jurisprudence.

"A substance which, on being applied to the human body, internally or ex-

ternally, is capable of destroying the action of the vital functions, or of placing solids and fluids in such a state as to prevent the continuance of life."—Black's Law Dictionary.

"A substance of definite chemical composition, which when taken into the living organism is capable of causing impairment or cessation of function."—Bouvier's Law Dictionary.

"Any substance which, when taken, applied to the body externally or in any way introduced into the system, is capable, without acting mechanically, but by its own inherent qualities, of destroying life."—Cyclopedia of Law.

"Any substance which, introduced into the living organism directly, tends to destroy the life or impair the health of that organism."—The Century Dictionary.

"In its scientific sense this word applies to any substance which, taken in small quantity into the body of a living animal, is capable by its chemical action, exerted locally or after absorption into the blood, of producing death or notable injury. This definition excludes substances which act mechanically, such as broken glass, or physically, as very hot water."—Century Dictionary.

Further definitions, selected from those elaborated by private authorities, are appended.

"A poison is defined as any chemical which when introduced into the body or generated within the body produces death or disease or permanently or temporarily impairs an organ that is healthy or apparently healthy."

"A poison is defined as any substance which when taken into the body in stated amounts, and usually in relatively small amounts, acting chemically, is capable of producing on ordinary persons, or an average person, death or grave injury to health."

"A poison is a substance, as we understand it, which when taken into the body, on account of its chemical constituent, seriously impairs or destroys the functions of some part of the body or it may kill, or simply impair."

"A poison is defined as any substance when introduced into the body in sufficient strength and in relatively small quantities and acting chemically is capable of producing death or serious injury to health in the case of an ordinary individual in average health."

"Toxicology is the science of poisons. A substance may produce deleterious results in several different ways. In the first place, it may act mechanically and produce disturbances in that manner. For instance, in the case of glass or other fragments, or by physical action as in the case of extremely hot water, or it may produce deleterious results by local chemical action which destroys the tissues with which it comes in contact, like sulphuric acid, or it may produce deleterious results by organized material which occurs in the system and produces detrimental results and it may act chemically upon the blood, or it may be carried by the blood to other parts of the body and there produce chemical action which is detrimental which is the case in true poisons; or substances can be taken in excessive quantities, substances naturally taken may also, when taken in excessive quantities, produce deleterious results by the increased quantity. For instance, you may take too much food of one kind or another."

It is plain to be seen that there is no unanimity of opinion in the best definitions at our command. Some definitions are so broad that one could hardly point out any single article and say, "It is not poison." Common salt is referred to by one of our prominent medical journals as follows: "A case reported in this issue calls attention to the well-known yet not always sufficiently recognized fact that sodium chloride, while the least toxic of the group of similar metal chlorides, is a *poison* which may be abused with fatal results." And from another issue of the same journal we learn that over doses of this same sodium chloride are commonly used in China as a means of committing suicide. One school thinks only of the *quality* of the physiological effect produced by any given substance; and if the effect is deleterious in any way then the substance is a poison. Another school thinks of the *quantity* of the effect produced; thus a small quantity of effect upon you might be beneficial, while a larger quantity of the same effect might be injurious. As an example a little strychnine might be beneficial, while more might be deleterious.

We should not overlook in our survey of the question the varying idiosyncrasy, or susceptibility of man and animals to certain articles. Poison Ivy is much more troublesome with some people than with others. The effects of buckwheat and strawberries on some people are familiar. Rabbits are said to withstand large doses of atropine. The hedge-hog is reported to withstand unusual doses of numerous articles that we commonly call active poisons. And are not birds quite indifferent to strychnine? These considerations only increase the difficulty of framing a satisfactory definition for poison, and at the same time increase the need for such a definition. There are hosts of articles generally regarded as harmless that should be classified as poisons if one is to follow the definitions, the laws, the court decisions, etc. It is not impossible to classify the various drugs and chemicals as to poisonousness, but no two people would do it alike. They would make up classifications widely different. Again the need for some one master classification is shown. And a proper national poison law would be such a master classification.

A proper national poison law would leave no doubt in the mind of the producer, dealer, or consumer as to just what articles are to be considered poisons and labeled and handled accordingly. With such a law it would not matter that one says chemistry and physiology know no substance as such which is deleterious to health, but every substance has a definite ratio to the weight unit of the human body below which it is without any effect, and above which it exerts its specific influence. It would not matter that some pronounce caffeine poisonous, while others proclaim it harmless. With a proper national poison law enacted everyone would be on an equal footing and one person would know as well as another whether any given preparation should be handled as a poison or not. In other words with a standard once set all would have an equal chance to live up to it.

Just what a national poison law should comprise is a subject that needs study. But certainly the law should be as definite as possible. It should not depend for its efficiency on such vague expressions as "active poison," "virulent poison," "acting in a noxious manner," "capable of producing deleterious effects," "liable to be destructive to adult human life," etc. If, as it appears, we can not now

define a poison, let us perhaps omit the definition and frame our law in some other way. Let us in the law enumerate the poisons by name. It will be a long list and an incomplete one. But to-day we have no list at all, so that even an incomplete list will be a step in advance. Let us authorize changes to be made in this list and additions to be made to it. By this means an article at first regarded as non-poisonous can later be put on the poison list. Our knowledge is constantly changing, so our poison list should. An article may be used some years before it is learned that it is habit-forming. In the beginning it would not be found on the list, but subsequently should be.

The law might be made to say such and such things are hereby declared poisons and must be treated in such and such ways. Just as our tariff laws contain almost unending lists of articles that must pay duty so and so. Perhaps classifications could be embodied in the law, as for example Schedule A—Habit-forming drugs, Schedule B—Heart stimulants, Schedule C—Emmenagogues, etc. But these schedules or lists are not sufficient without the individual poisons being mentioned by name (and perhaps also by quantities when in combination). If this provision could be made so that the three Secretaries (Agriculture, Treasury and Commerce) by means of appropriate advisers could keep the schedules up to date, we should have an effective statute.

Such an arrangement is not wholly new. Canada now has a law somewhat on these lines. But with us there would be much in it that is new. It will be necessary to decide what should be considered poisonous for practical purposes. It is easy to decide what is poisonous on purely theoretical grounds; but we live in a practical world. Still we have already made beginnings in establishing standards of poisonousness and we can go on. You are doubtless familiar with the interesting work along these lines using strophanthin made according to Thoms as a standard for comparison. A commission or a committee under the direction of the Bureau of Chemistry or perhaps of the Public Health Service would no doubt be able to do good work on this subject. It is to be remembered, however, that in a national poison law the aim is not to establish fine medical distinctions in regard to poisons, but to establish a working basis, a practical basis for traffic in poisons in interstate commerce of such a nature that consumer, dealer, and purchaser will be equally assisted and protected.

DISCUSSION.

H. H. Rusby, of New York, said he would like to add a definition: A poison is any substance which, introduced into or applied to the bodily tissues, is capable of producing death otherwise than by mechanical action.

C. T. P. Fennell, of Cincinnati, said the English law placed it on a much broader basis. The claim there was, that any substance which entered the human body and deranged any function was a poison. There was one substance which, recently, caused a great deal of trouble in Cincinnati, a substance not mentioned in any of these laws—barium chloride.

C. A. Mayo, of New York, said the question of poisons happened to be at an acute stage just now, the postal regulations regarding the shipments of poisons having been entirely upset by recent United States Court decisions, and the postal authorities seemed to be entirely at sea as to what should or should not be permitted in the shipment of poisons by mail. The regulations heretofore in force gave permission to shippers of poisons to ship only to dealers, but the United States Court had decided that these regulations were illegal. It seemed to

him that the Association was in a position to give counsel and advice to the authorities, and he thought it might help the situation to offer such advice; therefore, he proposed the following resolution for discussion in connection with this paper:

"WHEREAS, The regulations regarding the shipment of drugs by mail are vague, indefinite and unsatisfactory, and

"WHEREAS, The drafting of such regulations requires special knowledge of pharmacy and its problems. Therefore, be it

"Resolved, That the Chairman of this Section appoint a special committee of five to prepare such regulations and submit them to the postal authorities for consideration."

J. H. Beal, of Scio, Ohio, said he thought acknowledgment was due Mr. Murray for the very valuable paper he had presented. He knew something of the labor involved, because, some fifteen or twenty years ago, he had undertaken to find a definition of the word "poison" which could be used in the drafting of a poison law, and had searched diligently for all possible information on the subject. He had finally come to the conclusion that Mr. Murray seemed to have come to here, that the physiological or scientific definition of poison, based upon physiological action, would not do for a legal definition; that a legal definition of poison must be more or less arbitrary. Then he considered the question of whether or not such definitions as were found in the Pennsylvania Poison Law could be used, making the question of whether it should be labeled poison depend upon the quantity required to produce death, but the toxicologists were so much at variance upon this point that he had discarded the idea as impracticable.

He had finally drafted a bill, which had been enacted into law in the State of Ohio, and was still in force there. This law did one of the things which Mr. Murray had recommended, it attempted to enumerate the poisons. It began by stating that "The following substances shall be regarded as poisons:" and after enumerating a list of such articles, provided a series of exceptions, excluding certain insoluble substances that had never been known to produce poisonous or fatal results. Further study had convinced him that a satisfactory legal definition of the word "poison" would require the adoption of a standard toxicity unit—say, for instance, the minimum lethal dose in milligrams which would occasion the death of a white mouse of standard weight. He thought by experiment along this line a standard toxicity unit could be developed, and then the law could state that any substance which had a toxicity value of a specified number of these should be deemed a poison. Mr. Beal concluded by saying that he would demur strongly to Mr. Murray's suggestion that any body or committee of men be permitted to extend the list of poisons or take away from it.

H. P. Hynson, of Baltimore, moved to refer Mr. Mayo's resolution to the House of Delegates. He said he was always glad when he found that anybody else entertained an idea or conclusion that agreed with his; it always encouraged him. He was particularly glad to hear Mr. Beal and the author of the paper say that it was desirable to be specific in this matter of poisons, and refuse to accept any general definition. He would especially impress upon the young men in pharmacy that they should stand for a definite and specific definition as to poisons. He also thought that narcotic and anti-narcotic legislation should be likewise specific. He told of the troubles they had in Baltimore, with three anti-narcotic laws, a general State law, a poison law, and a city ordinance. This had resulted in great confusion for a while, but he had finally succeeded in getting out a line of interpretations which, in spite of prejudice, had been accepted. They had gone to their state's attorneys and judges, and asked them to accept this as an interpretation of the law, and thought that when they got them to accept such specific description of each drug their troubles would be pretty well over.

J. F. Windolph, of Norwich, New York, was impressed with the importance of taking some action along the lines Mr. Mayo had suggested. He had in his possession an official definition from the Postoffice Department as to what was considered a poison, and he thought the members would be impressed with the idea that the Postoffice Department needed some expert advice in the enforcement of its amended regulations. The department did not wish to carry out the law along technical lines, and it had issued a rule to the effect that a medi-

cine would not be considered a poison if it did not contain sufficient poison to render the composition a poison.

Adverting to his resolution just offered, Mr. Mayo said he wished to forestall objection to it, or any attack by Mr. Hynson, by saying that this resolution did not involve a question of policy on the part of the Association, and he hoped the Chairman of the House of Delegates would agree with him in thinking that it was simply asking for the appointment of a special committee of a technical nature. He thereupon re-read his resolution, and said that the definition just recited by Mr. Windolph gave a good idea of what pharmacists had to go up against when it came to the postal authorities.

W. C. Abbott, of Chicago, said it seemed to him that, as an example of vague legislation—of which there had been a great deal—this attempted poison legislation stood out first. He regarded the proposed regulation of the Postoffice Department to declare all poisons un-mailable as little less than silly. It was an attempt to regulate the practice of those who knew a great deal more about the substances classed as poisons than those making such regulations. He believed that the purpose of the proposed regulation of the department was intended to protect the public, but this piece of "bureau legislation" was so widely general that it stood as a dead letter in practice, because it could not be enforced; or, if enforced, could only be so enforced to the detriment of the many, and would not be in harmony with the real purport of the law. He held that neither the pharmacist nor the physician should be handicapped in the manner he procured or prescribed poisonous substances, or potent remedies of any sort or character. What mattered it, in his business whether he got it by mail or express. At last, it was up to the educated pharmacists and physicians to handle this question properly. He heartily seconded the resolution offered by Mr. Mayo.

Speaking again on the subject, Mr. Windolph said he understood that the Criminal Code, section 217, excluded poisons, but gave the Postmaster General power to formulate certain rules and regulations for the admission of certain of these poisons, and the regulation which had been amended to conform to the court's decision, apparently did not admit any medicine containing poison, because the words "containing poison" had been omitted from the regulation, which now read that "medicines and anaesthetics" might be admitted. It was further provided that the word "medicine" should not be understood as meaning "poisons;" and according to the law and regulations attempting to make an exception thereto, it was not possible to legally mail any preparation containing a trace of poison. However, it was the purpose of the Postoffice Department to permit the mailing of preparations containing a minimum amount of poison. They were very much in the dark, he said, and didn't know just what they did mean. The definition had been given to him, that what was meant was a poison which, in the ordinary dose, was not fatal.

Mr. Murray said this discussion simply bore out the position that no one knew what a poison was, and the pharmacists did not know where they stood in this matter. His idea about the Postoffice Department was that they knew no more than the pharmacists, although they would like to know. He had with him a copy of the ruling of the department, to which Mr. Windolph had referred, which read: "Medicines containing a small proportion of poison are mailable, and medicines containing poison to such a degree as to make the composition a poison are not mailable." He said he did not understand what Mr. Beal meant by saying that this was not desirable.

Mr. Beal replied that he did not deem it advisable to give to any bureau the right to arbitrarily extend or diminish the list of substances which shall be deemed poisons, i. e., that he did not believe in "bureau-legislation." He was not referring to the postal regulations.

DRUG PRODUCTS—THE LAW AND THE LABEL.

LOUIS EMANUEL, PITTSBURG, PA.

How to make a statement of the strength, quality or purity on a label for drugs which differ from the official standards, in such manner as to be plain, has never been judicially determined. It is claimed by some that a simple declaration of the actual strength is sufficient, while others contend, that some qualifying statement should also be made in order that the purchasers may not be misled.

The labels employed by some manufacturers and dealers give evidence of their conviction, that a simple statement of the strength of the drug, in such cases, does not comply with the law. Examples:

"Aconite Root

Standard Strength U. S. P.0.5% Aconitine
Assayed Strength0.485% Aconitine

"Elixir of Ammonium Valerate

Alcohol, 17%

Each Fluidounce contains

Ammonium Valerate16 grains
Tincture of Vanilla 2 minims

This elixir is preserved with alcohol and glycerin. The chloroform of the N. F. preparation has been omitted and the elixir colored with carmine."

"Beef, Wine and Iron

Alcohol 18%

This preparation should not be confused with that of the National Formulary, as it is made from a different formula.

Each fluidounce represents 15 grains of Extract of Beef in Sherry Wine with about 4 Grains of Iron and Ammonium Citrate."

Section 7 of the Federal Food and Drugs Act provides: "That no drug defined in the United States Pharmacopœia or National Formulary shall be deemed to be adulterated * * * if the standard of strength, quality, or purity be plainly stated upon the bottle, box or other container thereof, although the standard may differ from that determined by the test laid down in the United States Pharmacopœia or National Formulary."

Section 8 provides: "That the term 'misbranded,' as herein used, shall apply to all drugs, or * * *, the package or label of which shall bear any statement, design, or device regarding such article, or the ingredients or substances contained therein which shall be false or misleading in any particular."

The label for a drug sold under an official name, which is either above or below the standard, having upon it a declaration of strength only, is plainly misbranded, because a single declaration of strength does not provide a plainly stated declara-

tion of the quality. Moreover, when such a label carries a guaranty, the label is misleading. The standard is stated and the drug guaranteed. Nothing appears on the label to show the purchaser what the standard should be. He does not know what the standard is and, naturally, concludes that the article is guaranteed of standard strength, but is sadly misled. In fact just such a case as this was brought to light in the work of the Pennsylvania Board of Pharmacy.

A prescription for Essence of Pepsin, N. F. was sent to a pharmacist who filled it with a nearly half-strength drug. Later this pharmacist was cited for a hearing before the board, at which he set up the claim that he was in the right and safe from prosecution because the essence he used was guaranteed by a reputable manufacturer. The difference in a guaranty *for what the product is sold for*, and a guaranty that the product is of *official standard of strength and quality*, misled him. This would not have been possible, if a declaration of the quality had appeared upon the label of the article, or a statement such as appears on the label for the beef, iron and wine, or the elixir of ammonium valerate quoted herein.

It may very properly be said that a pharmacist should be sufficiently familiar with official standards, to readily detect a drug of deficient strength when a simple statement of strength appears upon the label. But is this law for the protection of the pharmacist only? How about the physician and the general public, are they expected to know the standards? What constitutes a plain statement of the standard of strength, quality, or purity, within the meaning of the law?

For our answers to these questions we must look to the intent or purpose of the provision. It can have no other purpose than to protect the consumer and acquaint him with the fact, when he is sold an article that is not standard. A label bearing a statement of strength by which only the pharmacist may determine the actual strength and quality of the drug it represents, and that, perhaps, after making a careful calculation, cannot possibly afford the protection this provision is intended to give, to the ordinary every day purchaser of the product for his own consumption. The following illustrations will show how some manufacturers attempt to comply with this very important provision as to the label, and how the public may be misled thereby.

"Essence of Peppermint

Contains 80 percent PURE PROOF SPIRIT

19.75 percent Distilled Water

Pure Oil of Peppermint and herb, a trace.

Guaranteed under the Food & Drugs Act, June 30, 1906."

"Tincture of Iodine

Contains 45. percent Pure Alcohol.

3.51 percent Pure Iodine

0.5 percent Pure Potassium Iodide.

Guaranteed under the Food & Drugs Act, June 30th, 1906."

Under labels as above, drug products are not guaranteed for their PRIME quality. They are really guaranteed to be of inferior quality. The labels are not plain as to this, but what average purchaser of such 10 percent bottled prod-

ucts as these were taken from would ever know how utterly deficient in strength and quality they were?

The labels declare the strength, but say nothing plainly about the quality. They are not adulterated drug products, within the meaning of the law, but they are misbranded, which is, also, a violation of the law.

It is evident that there is need for a court decision in this matter and a possibility of a common sense rendition, as to what a plain statement for sub-standard drugs should consist of, is apparent, when we consider what Chief Justice Claybaugh, in the Antikamnia case, says regarding regulations, viz.:

"Conceding for the purpose of the statement of this case, that this is not a quasi-criminal statute, but purely a remedial one, if that be true then it is the duty of the court to construe it as to give effect to the purposes and objects for which it was passed.

"I have no doubt that these secretaries could, with great propriety, make regulations that would more effectually carry into execution the purposes and intent of the law makers. That being so, what is the fair construction of the act, or does it need any interpretation?

"The right to interpret an act in conformity to the purposes and objects of that act applies only where the act is not perfectly plain or is not perfectly apparent.

"Then the courts can give such interpretation to it as will carry out and gratify the purposes of its passage. Interpretation, as I understand it, does not mean that the court can add anything to language which is plain."

This would seem to encourage a hope that the position taken by the Pennsylvania Board may be sustained when properly presented to the courts.

Regarding regulations. The Federal law does not provide for a guaranty and serial number; nor does it provide, that a label shall make reference to a guaranty; nor does it provide that a guaranty shall be filed with the department of agriculture, but the regulations adopted, do provide for, not only the guaranty and serial number, but also the manner in which these are to be stated. It was found when left to themselves, manufacturers misapplied the object of the guaranty and made their labels read "Guaranteed by the U. S. Government."

Now if it is legal and proper to adopt regulations as to the manner in which a guaranty shall be made, and stated, it is reasonable to hold that regulations may be adopted which shall provide for a plain statement for labels on sub-standard drug products, in order that purchasers may not be misled.

SOME PHASES OF A PHARMACIST'S DUTY TO THE PUBLIC.

ZADA M. COOPER, PH. G., IOWA CITY, IA.

It is fair to suppose that all men realize that they owe something to the community in which they live. They believe that it is their duty to be good citizens but the ideas of what constitute good citizenship are as far apart as the poles. It is without doubt too often true that men think it is sufficient to be honest and honorable in their dealings with others, to pay their debts and keep out of the penitentiary. There is a considerable number who do not even feel it a duty to exercise the right of suffrage. In brief, it is a passive sort of good citizenship

that they practice, feeling no compulsion to engage in active service for mankind in general or their neighbors in particular, and, I suspect that pharmacists are not altogether innocent of such inactivity.

Lest such a criticism from a woman seem rank presumption which it probably is, I hasten to say that it is of only one specific point that I wish to speak and that point is just as applicable to myself as to others. I refer to what we as pharmacists should do toward the education of that part of the public with whom we come in contact. We shall all concede that we are our brother's keeper in so far as it is necessary to supply him with only good drugs and medicines and to refuse to sell him dangerous habit-forming drugs, but how many of us feel any necessity to help him to a better understanding of these things, how many of us try to pass on useful knowledge? Do we believe with Huxley that while, "We live in a world which is full of ignorance and misery" it is "the plain duty of each and all of us to try to make the little corner he can influence somewhat less ignorant than it was before he entered it."

Possibly there is no subject of which the public is so ignorant as medicine, unless it be religion. Not even in religion is there more superstition, more absurdity, more need for the exercise of common sense and good sound reasoning.

Little can be accomplished in the way of reform by legislation or otherwise along any line without an awakened public sentiment and before public sentiment can be aroused, the need of reform must be seen, there must be knowledge, education. Take for example, the patent medicine evil. It can never be eliminated without a campaign of education. Just as long as the public reads the alluring advertisements and believes the extravagant claims, we shall have the thing to contend with. Efforts to get restrictive legislation come to naught so long as the people believe in the efficacy of such remedies. Until they learn that most of them are worthless if not dangerous they will continue to use them. Some lay magazines have done much toward exposing them but there is still a vast amount of ignorance and, in my opinion, it is the duty of the pharmacist to do what he can to reduce it. It is not expected that we shall be able to eliminate the sale of patents entirely or that we shall refuse a customer who insists. We cannot bring in the millennium instantly but it is unnecessary to push that branch of the business. Even if we are to consider it only from the mercenary view point, the same effort expended on some other department would bring better results.

Of course we all understand the difficulties that will be encountered. For various reasons, some people resent pharmacists offering information. It may be the implied ignorance, an unusual amount of conceit, or the impression that it is an interference in one's private affairs. Whatever the cause, it involves the exercise of tact but so does the successful conduct of any part of your work. In fact any profession, any business, any trade, in which one must deal with people, I care not what it is, requires that same quality if one is to get on. The ability to estimate human nature is very essential in any branch of the pharmacist's calling, hence there can be no good reason for not bringing it into use here. Then as opportunity offers, should not a pharmacist teach many of the dangers of self-medication?

Should we not go a step farther and try to explain that self-medication usually

involves self-diagnosis. If they can be made to understand that standard remedies of well known therapeutic value are best, perhaps they can be taught also that they cannot diagnose their own ailments and that that is just what a physician is qualified to do. Attention can be called to the fact that a prescription is a safeguard against error because at least two people, the physician and the pharmacist see it before the medicine gets into the patient's hands. The public should know that if a dispensing physician makes a mistake, it is difficult to prove and so there is less chance of recourse. Perhaps we hear it said, "The Lord giveth and the Lord hath taken away" when as a matter of fact the Lord had nothing to do with it. In the case of the physician who prescribes, errors are much more easily located and the prescription itself is evidence. What is still more important than being able to trace mistakes is the fact that error is much less likely to occur. If it be the physician's the pharmacist should detect it, if it be the pharmacist's the checking systems usually employed in reliable pharmacies reduces the chances to a minimum. I am sure that pharmacists have no desire to antagonize physicians but these are a few of the things the public has a right to know, things upon which they have thought little but knowledge of which would materially affect the attitude of intelligent thinking people. Another of these little known facts is that the pharmacist's stock must conform to the requirements of pure drug laws but physicians may dispense what they please and no one is the wiser.

I believe that teachers of salesmanship agree that one of the essentials is a knowledge of the stock. If the sale of ordinary merchandise is helped by knowing all about it and subsequently passing on to the customer at least a part of that knowledge, surely the principle is just as applicable to the sale of many things handled by the pharmacist, even to many drugs themselves. I believe the old idea that the less a man or woman knows about medicine the better, is all wrong. We shall grant that technical and professional information is only for those educated in the profession but outside of this there are a great many interesting and helpful facts about even the common household remedies that can easily be passed on to the customer. In an article by Mr. Raubenheimer published not long since he gives an excellent example of how historical information about sulphur, cream of tartar and Rochelle salt displayed on placards in the show window aided in the sale of lozenges compounded from these ingredients.

Having good laws regulating the practice of pharmacy is a benefit to us but many of the laws were enacted primarily for the protection of the public. So what is good for the public in the end benefits us—the knowledge we pass on to them brings returns. "Cast thy bread upon the waters" is not without its application here. Some one will say that it does not pay to go to so much trouble, that it is a thankless task. I believe not, I believe it will react to benefit us either as druggists or as citizens. The simple fact that you know increases the respect for you and your calling. Every man owes it to himself to bring his vocation to a higher plane of honor and usefulness. As educated men and women we owe the community more than the uneducated. Some one has said that, "Education is the development of power to bring things to pass for the common good." If that be true, we do not know that we are educated, we have no right to the

title until we make use of our power, latent though it may be, to do something for the common good.

There is no lack of opportunity to exercise this sort of good citizenship. If there seems to be none, it is because we are so self-centered as to be blind to our opportunities. In advice about sanitation and methods of disease-prevention we should be able to do much toward assisting public health departments. It has been said by one of our own number that "no trade or profession of the present day presents greater opportunity for serving the human family by relieving suffering and causing the dissemination of useful knowledge than that of the pharmacist."

Apparently physicians themselves believe that the public needs information and have claims that those who possess the information have no right to ignore. Not long since an editorial in the Journal of the American Medical Association emphasized the people's right to a thorough education in the "essentials of public and personal hygiene and sanitation" and "to correct information about medical progress." Another physician writing recently says that "the education of the laity on medical matters is daily becoming a subject of wider interest and greater importance. Preventive measures are based in great part upon a thorough medical education of the public." Among those who are most likely to be asked to express opinions concerning medical questions, he includes the druggists and thinks that druggists who are asked for advice or to express an opinion as to the meaning or seriousness of any symptoms can be of much assistance to physicians, that he has done as much perhaps as the physician himself if he advises against the use of remedies that may be of doubtful value and succeeds in bringing the case to the physician's care.

INTRODUCTION TO THE REPORT OF COMMITTEE ON PATENTS AND TRADE-MARKS.

F. E. STEWART, M. D., CHAIRMAN.

In June, 1881, your chairman, then attending the annual meeting of the American Medical Association for the first time read before the section dealing with the *Materia Medica*, a paper entitled, "The *Materia Medica* of the Future," and in connection therewith he laid down as a declaration of principle the following resolution:

Resolved, That it is contrary to the spirit of the code of ethics for a physician to prescribe a remedy controlled by a patent, copyright, or trade-mark. This, however, shall except the use of a patent upon a process or machinery for manufacture. It shall also accept the use of a trade-mark if the article so marked is provided with a technical name, and a working formula, under which any person may manufacture and sell it.

This resolution was rejected by the Judicial Council on account of its exceptions, it being considered contrary to the spirit of the code of ethics for physicians to habitually prescribe, or in any other way endorse the commercial control of anything required for the prevention, cure or mitigation of disease. It is unnecessary to add that if the medical profession had been true to its obligations,

pharmacy and drug therapeutics would today possess much higher standing in the estimation of the public than at the present time.

Long before the advent of the modern manufacturing houses engaged in the pharmaceutical field the so-called "new remedy" business had its birth in the retail drug store, and was known as the "specialty" business. Many of the so-called specialties originated as favorite prescriptions by leading members of the medical profession. Some were labeled with descriptive names, others with semi-descriptive coined names which were generally adopted as proper titles. As a rule labels were provided with names of diseases and doses, frequently with circulars setting forth their uses, all intended for the convenience of the self-medicating public.

As long as this method of doing business was confined to the retail druggist it was not only considered legitimate, but proudly heralded as "elegant pharmacy," and the reputation of the pharmacist among the members of his guild was largely dependent upon the sale of his specialties. The medical profession prescribed them, the demand created thereby increased their sales, and the endorsement of physicians gave sanctity to the business.

But when the country became over-run with unlicensed practitioners parading as manufacturing pharmacists and chemists, who advertised similar preparations in the medical journals and sent out their detail men to interview the doctors, then a mighty howl went up from the retail druggists, and the Brooklyn Formulary, which afterwards became the National Formulary, was devised in retaliation. Shortly afterward a corresponding howl was raised by the doctors. They commenced to take exception to the methods of labeling, circularizing and advertising. Attention was called to the fact that physicians who prescribed this class of products, prescribed themselves out of practice, and sent their patients to the nostrum manufacturers for treatment. The advertisements were characterized as tissues of fraud, humbug and lies. Then it was discovered that some of these products were patented, others commercially controlled by registering their currently used names as trade-marks, and others by secret or semi-secret formulas and processes. These discoveries brought out the fact that the "specialty" business was only another branch of the so-called "patent" medicine business, the principal difference between them being that one class of products was advertised in the secular and religious press to fool the people, and the other class advertised in the medical journals to fool the doctors.

Your chairman graduated from the Philadelphia College of Pharmacy in 1876, under the tuition of preceptors prominently identified with the "specialty" business, and, after graduation, went into the same business as a proprietor, later graduated at the Jefferson Medical College, class of 1879, sold out to one of the prominent manufacturing houses, entered the practice of medicine, and made an arrangement for receiving royalties for new materia medica products of his own introduction. His literature was reprinted from the medical journals by said house and widely circulated to the medical profession. The products were not patented, or "trade-marked," and full knowledge concerning their method of manufacture was published in the medical press, but in spite of such precautions to be ethical, immediately the leaders of the medical profession in New York took exception to this action upon the part of your chairman and the

manufacturing house referred to. As both had gone into the arrangement in good faith, both now united in an attempt to solve the problem presented by the so-called "new remedy" business.

The "propaganda for reform" agreed upon included the following:

First.—A published platform declaring the policy of the propaganda, and including the objections urged by the profession against the new remedy business.

Second.—The advocacy of the establishment of a national bureau of materia medica, or board of control, under the central government at Washington, provided with laboratories for materia medica research, and including government experts employed in the various government departments dealing with medicinal drugs, chemicals, or preparations of the same, and also including the physicians in the Army, Navy, and U. S. Marine Hospital Service engaged in research work.

Third.—The investigation of the materia medica of the world by said government bureau to ascertain what products were being used by the various nations, peoples, and tribes, with the object of adding the same to the materia medica collection in the National Museum, and whenever any product was discovered appearing to be worthy of further research, the same to be investigated by the laboratory and its claims proved or disproved.

Fourth.—The organization of a National Pharmacologic Society, representative in character, including members of the medical and pharmaceutical professions, and manufacturers engaged in the pharmacal and chemical industries, also editors and publishers of medical journals, the special object of the association being to co-operate with the bureau or board of control.

Fifth.—The free publication of working bulletins by said bureau or board containing all available information concerning each product undergoing more complete investigation, the same to be sent to clinicians throughout the country for the therapeutic test of said products, in the form of properly prepared and standardized preparations, to be furnished by the government without charge.

Sixth.—The publication of a monthly journal, an annual report, and a complete compilation of the results of work done in book form.

Seventh.—The abolishment of commercial monopoly of materia medica products except in so far as limited monopolies may be obtained by the proper application of the patent and trade-mark laws.

Eighth.—The establishment by the manufacturers of Scientific Departments manned by persons skilled in the arts of medicine, pharmacy and chemistry, including physicians, pharmacists, chemists, physiologists, botanists, bacteriologists, etc., such departments to be professionally organized as a part of said pharmacologic society, and working in co-operation with the bureau or board of control.

Ninth.—The introduction into the Pharmacopœia of methods for standardizing galenicals, thus extending and making more practical the work of the revision committee.

The results of this propaganda have been far reaching. The Smithsonian Institute endorsed the plan for an investigation of the materia medica of the world under governmental auspices. It was also endorsed by the Surgeons General of the Army, Navy and U. S. Marine Hospital Service, also by the Alumni Associa-

tion of the Philadelphia College of Pharmacy. It was discussed by the Philadelphia County Medical Society and approved by H. C. Wood and other prominent men in the medical profession both in civil and official life. The American Medical Association memorialized Congress on the subject in 1891. The A. Ph. A. in a set of preambles and resolutions endorsed the policy mapped out by our Committee on National Legislation in 1896 in relation to the commercial control of materia medica products. This act was in accord with the Richmond resolution. The Journal of the American Medical Association editorially endorsed a modification of the bureau plan presented by your chairman in April, 1901. Several of the large manufacturing houses adopted the scientific department idea, and also adopted the working bulletin system under that or some other name. The U. S. Pharmacopœial Convention increased the scope of its standardization work by introducing standardized galenicals in 1890, and made further additions in 1900. In 1901 a national pharmacy company was incorporated in New Jersey and organized in San Francisco, and a national bureau of medicines and foods organized to support it. This plan was cordially approved by the leaders in pharmacy and medicine on the Pacific Coast, but afterwards abandoned to take part in an organization under the auspices of the A. M. A., and A. Ph. A. The joint committee reported favorably but the plan was defeated, only to rise again in another form as the A. M. A. Council on Pharmacy and Chemistry.

It is safe to assert that the combined manufacturing houses of the United States engaged in the pharmacal and pharmaco-chemical industries publish and distribute to the medical profession at least fifty tons of literature annually relating to their products. This probably represents two or three million or more separate working bulletins, pamphlets or circulars. The question is, are these publications disseminating truth or error? If truth, then the publication represents a work most beneficial and salutary. If error, then these houses are misleading the medical profession, exploiting the sick for gain, and are guilty of a heinous crime against humanity.

The object of the scientific department idea referred to in this report, with its working bulletin system for the distribution of scientific literature concerning the newer materia medica, the same to be published under the censorship of a bureau or board of control, representing the several interests involved, is in line with the professional society idea in which individuals contribute the results of their experience and observations for the benefit of the profession, and submit their contributions to the censorship of their peers, who censor the same in organic capacity. The literature of contributors to the professional societies, describing results obtained from original research, may be copyrighted, but the results of their investigations are freely given to the profession. Progress in the science and arts of medicine is thereby promoted because each member of the profession who does his duty uses the knowledge thus contributed and publishes the results of his observations also, thus verifying or disproving the findings of the original contributors.

The object of the patent law is to promote progress in science and useful arts. This object is now being defeated by the way our patent and trade-mark laws are being interpreted and applied in the protection of alleged materia medica inventions. As not over one-tenth of one percent of the alleged new

remedies commercially introduced during the past thirty years and protected by patents and so-called trade-marks have proved of sufficient merit to justify the experiments upon the sick entailed, it is evident that these laws have been misinterpreted and misapplied. Is it not about time that we as physicians and pharmacists enter our protest against such travesty of law? And in making this protest, could we make it more effectively than to adopt a plan for directing this great commercial propaganda, employed for creating a demand for these alleged new remedies, into proper educational channels for the circulating of accurate information concerning them, by establishing a censorship over the publication of this literature—a censorship voluntary and representative in character on the part of the manufacturers, and co-operative on the part of the medical and pharmaceutical professions?

Place the professions where they can properly co-operate by making the propaganda professional in character and there will be quick reciprocity on the part of professional men. But the professions cannot co-operate with a plan for using the professions and the public for selfish purposes.

Finally, the professional ideal of pharmacy includes autonomy on the part of the profession. Without autonomy there can be no profession of pharmacy. We have our professional schools, press and societies, but are lacking in the essential qualification necessary to gain for the vocation recognition as one of the liberal and learned professions, namely, autonomous censorship and control over the publication of literature relating to the introduction of new materia medica products to be used by the medical and pharmaceutical professions. Such autonomy is secured in the publication of information relating to the older materia medica by the Pharmacopœial Convention and its Committee on Revision. Why not establish a similar board of control for the censorship of literature relating to the newer materia medica?

From the above statement it will be seen that the question of patents and trade-marks as applied to materia medica products is entirely subsidiary and dependent upon questions of materia medica standardization, professional autonomy, and medical and pharmcal education and license. Some of these questions are:

Who shall practice medicine and pharmacy, licensed practitioners duly qualified by education and license from a board of examiners, or unlicensed practitioners who have set up as manufacturers and are practicing at wholesale at long range and without diagnosis?

Who shall control the teaching of therapeutics as applied to the newer materia medica?

Who shall decide questions relating to the preparation and standardization of these products?

How shall the patent and trade-mark laws be so applied as to promote progress in materia medica science, advance the legitimate practice of the arts of pharmacy and drug therapeutics, and protect the public from the errors of dishonest commercial exploitation?

How shall charlatans and pretenders be prevented from availing themselves of the protection of these laws in carrying on a dishonest commercial business parading under the guise of scientific pharmacy and chemistry?

Is it not apparent then that we need some kind of bureau or board of control or society, representing the several interests concerned, in which the autonomy

of the medical and pharmaceutical professions can be vested in relation to the newer *materia medica* just as they are now vested in the U. S. P. Convention and its committee of revision in relation to the older *materia medica*—a bureau or board working in co-operation with the professions and manufacturers for the promotion of the common good and public welfare? Can the American Pharmaceutical Association take up the work and secure the aid of the manufacturers in establishing a home for the Association with proper laboratories and facilities? Ought the work to be assumed by the Pharmacopœial Convention at its next decennial meeting? Or would it be a better plan to have the work taken out of the hands of the professions and assumed by the Federal Government? Upon the answers to these and other questions relating to professional autonomy is dependent the answer to the patent and trade-mark question.

There seems to be so much misunderstanding in regard to the object of the "propaganda of reform" advocated so persistently and consistently since 1881, that your chairman feels it incumbent upon him to make this preliminary statement.

REPORT OF THE COMMITTEE ON PATENTS AND TRADE-MARKS.

The question of patents and trade-marks in its relation to medicine and pharmacy is far more complex and comprehensive than the superficial student realizes.

The physician and pharmacist have already been granted a monopoly of medicine and pharmacal practice. This grant was given in exchange for services of a highly altruistic character. There is no justification for either calling, except to the extent that the practitioner is able to prevent disease, relieve suffering, and heal the sick; and the function of the pharmacist is to prepare medicine for the physician to use, also to meet the demands of the public for medicine for self-medication so long as these demands are within reason.

Why should the government grant to the ignorant and venal manufacturers and dealers in drugs the right to the exclusive sale of certain *materia medica* products on the ground that they are "new and useful inventions and discoveries" in the treatment of the sick, and thereby create and foster great medical monopolies conducted in an unfair competition with the medical and pharmaceutical professions, and in a manner inimical to the public health?

In reply to this question we are constantly confronted with the answer: "What are you going to do about it?" If the medical and pharmaceutical professions would get together and ask Congress to do something about it, it would soon be done. As stated by one of our prominent senators: "Congress is always ready to listen to the advice of the learned professions, especially in regard to legislation concerning the practice of these professions. That is what Congress is here for. But we as legislators can do nothing until you, as professional men, agree as to what you want done."

Contrary to the general impression, the inventor does not possess a natural right to the exclusive use of his invention. The right, when it exists at all, is a creature of statute and grant, and subject to the conditions imposed by the

statute and the grants. The government is under no obligations to grant inventors the exclusive right to their inventions or discoveries. The object of giving such grants is to promote progress in science and useful arts.

Is the patent system now in vogue, as applied to medicine and pharmacy, promoting progress in the science of materia medica and in the arts of pharmacy and drug therapeutics? When it is considered that thousands of alleged new remedies have been introduced during the last thirty years and not one-tenth of one per cent of them has proved of any special therapeutic value; when it is considered that this introduction represents hundreds of thousands of useless experiments upon the sick by physicians in private and hospital practice, and many times that number by the self-medicating public, it is evident that the question may be properly answered in the negative.

Why should materia medica products be patented at all? Apparently the only persons who have profited from these patent grants have been the manufacturers of the patented products and the medical journals accepting their advertisements. It is well known that, as a rule, these advertisements are misleading. In no line of business is the principle underlying the motto "*caveat emptor*," (the purchaser beware) been worked to such an extent as in the introduction of alleged new remedies by advertising.

The system has debauched the medical and pharmaceutical press, has seriously injured medical and pharmacal practice, has thrown pharmacy and medicine into disrepute with the public, and has proved a serious detriment to the public health. The medical press itself would be far better off under a system of open competition between manufacturers of new materia medica products. Take diphtheria antitoxin for example, it is an open product, consequently there are a number of manufacturers each contributing to the advertising columns of the medical journals. Adrenalin, on the contrary, is a closed product controlled by a product patent and for seventeen years there can be but one brand of it and therefore only one advertiser. Why should we sacrifice the professions of medicine and pharmacy, and the public health for the advantage of the manufacturers of questionable therapeutic novelties, and medical journals subsisting upon their advertising patronage? Why should not the system be wiped out altogether?

Most foreign countries prohibit the patenting of materia medica products, but as a rule permit the patenting of processes and machinery for their manufacture. Germany has been one of the leading countries in this respect. But now Germany will probably modify its patent law to be in line with the United States patent law, so that all of the arguments based upon the example of Germany will, in that event, fall to the ground.

Fortunately the advertising fraternity are waking up to the menace threatening the advertising business due to the misleading character of advertising in general. "Printer's Ink," the well-known organ of the advertising fraternity, is advocating a Bill for the prevention of misleading advertisements. This bill, or legislation founded thereon has already been enacted in several of the states, and it is hoped that it will be universally adopted by all of the states of this Union.

The Shirley Bill, recently passed by Congress, has for its object the suppres-

sion of misleading advertising in so far as it relates to foods and drugs in interstate commerce. If these laws are properly enforced the result will be to make the advertising of medicines as now carried on by some manufacturing houses exceedingly unprofitable, both as to reputation and financial returns.

One of the most important points in regard to the patenting of materia medica products for the protection of the commercial introduction by advertising is this, namely: materia medica products cannot be properly introduced by advertising. The only way they can be introduced in such a manner as to promote progress in the science of materia medica and the useful arts of pharmacy and drug therapeutics is by the co-operative investigation of experts in the various branches of knowledge upon which materia medica science depends.

The services of experts in pharmacognosy, pharmacy, pharmacodynamics, therapy dynamics, and pharmacotherapy are required for their introduction. It is necessary to develop a knowledge of their source or genesis, physical and chemical properties, methods of selection, preparation, reservation, compounding and dispensing, and also a knowledge of their comparative value in relation to the older products of the materia medica used for similar purposes. This in turn requires co-operation between the laboratories of the universities, government institutions and manufacturing houses engaged in the legitimate pharmacal and chemical industries. Therapeutic verdicts concerning new medicinal products can only be obtained by the co-operative investigations of many competent observers extending over years of time, and conducted under conditions of environment sufficiently differing as to climate and nationality so as to eliminate the personal equation. It is manifest that this is an altruistic work in which all co-operate for the common good, and that the results of the co-operative work belong to the professions of medicine and pharmacy, and to the public, and do not belong to individuals for their exclusive use. Why should we permit individuals, firms and corporations to monopolize common property for personal gain?

Taking the above facts into consideration, it would seem that the American Pharmaceutical Association should consider the subject of materia medica monopoly from the point of view of the public, and not from the narrow and selfish viewpoint of individuals. As before mentioned, pharmacy and medicine have lost caste because of the narrowness and selfishness of the professions themselves, and the only way to restore public confidence in physicians, pharmacists, and medicines is for the professions to unite with the legitimate pharmaceutical and chemical laboratories in an appeal to Congress for the proper legislation on this subject.

Mr. Bodemann, member of our Committee, calls attention to the fact that our present patent law as applied to materia medica, not only "does *not* encourage scientific research, but absolutely forbids it; that is to say, if you find a way to make a certain product and then patent it, I am not allowed to make the same product even though I may have discovered a better way for so doing."

This undoubtedly is true, and your chairman has since 1889 continually called attention to the fact in his reports, in literature, and in his reports as Chairman of this Committee, and Chairman of a Special Committee on National Legislation.

What shall be the character of this legislation? This is an important question, and apparently it will be very difficult to harmonize the conflicting interests involved. Several excellent suggestions have been made, one of the latest of which emanates from Joseph England, Secretary of Council of the American Pharmaceutical Association, and a member of the Committee on Patents and Trademarks. Mr. England suggested at the recent meeting of the Pennsylvania State Pharmaceutical Association, after listening to the report of the Committee on Patents and Trademarks, that said Association should appeal to Congress for the modification of the patent law, giving the Commissioner of Patents the right and authority to suspend or abrogate a product patent, or any materia medica product if an inventor of an improved process for its preparation shall apply for a patent therefor.

The effect of this plan would be quite similar to the effect of the clause in the German patent law which places the burden of proof in cases of infringement of process patents upon the inventor of the alleged improvement, forcing him to show that his process is in fact an improvement upon the original process for the preparation of the drug in question.

The question of trademarks is largely a question of interpretation of law. Trademarks used to distinguish between brands of well-known articles of commerce, each provided with a name of its own for proper classification and use in medical and pharmaceutical literature, is to be strongly commended. But the scheme for creating a monopoly by registering as a trademark a coined name and afterwards using it, not as a brand mark, but as the name of the article itself, is to be strongly condemned. Any person has a perfect right to make and sell any article of commerce provided he knows how to do so, also to deal in it under its currently used name. If it were true that the first commercial introducer of an invention acquires thereby a proprietary right in the product, or in the name of the product, there would be no necessity of a patent law granting him the right to the exclusive use of his invention, for he would already possess such a right by nature, and the laws would be so formulated as to protect him in his natural right. Moreover, the right to the exclusive use of the invention would be perpetual in character, and in its enforcement powerful monopolies would be created, unlimited in time and possessing privileges far more influential than any granted by the patent law. If the world had started in this way every art would now be subjected to monopoly and inventors would own the world; the rest of us would be their slaves.

The trademark law does not recognize any such scheme as the one described. In fact, the trademark law does not attempt to define what is meant by a trademark. This has caused much misunderstanding on the part of the Patent Office and the courts. Not many years ago one of the leading members of the Illinois Bar, in defending a case before the Supreme Court of the United States, asked the court for a definition of the trademark. He said: "I have searched the literature on this subject for a definition and found none," and he requested the court "for the sake of the Bar, the Bench, and the commercial interests of the country to define the word, trademark." The court did not respond to this appeal.

Fortunately many of the recent decisions of the Supreme Court have cleared up

mooted points in relation to the patent and trademark systems. In 1895 the Supreme Court decided that the names of patented products could not hold as trademarks after the patents expire. This was decided in the Singer Sewing Machine case. More recently the Supreme Court decided that the patentee has no right to dictate as to what article should be used in connection with his patented article. This was decided in the Mimeograph case, and referred to in our report last year. Still more recently the Supreme Court decided that the patentee has no right to dictate the price at which his patented product shall be sold by the purchasers. This was decided in the Sanatogen case, Bauer et Cie, of Berlin, Germany, co-partners, being the signers of Letters Patent of the United States, dated April 5th, 1898, No. 601995, covering a certain water-soluble albuminoid known as "Sanatogen."

Finally as to the names of unpatented products, there has been a large number of decisions to the effect that the name of an article does not belong to the person who christens it, but to the article itself as a common noun. Any person has a right to make an article, has a right to manufacture and deal in it under its currently used name. It is to be hoped that this question will come up before the Supreme Court in a clearly cut case when the court can decide this question once and for all.

Another point in this connection is that relating to the defense of trademarks. The courts require that persons desiring to defend their trademarks shall come into court "with clean hands." This they cannot do when they have been guilty of misstatements on labels or in literature relating to the products in question.

The Supreme Court of the United States in the case of Worden versus California Fig Syrup Company, threw the case out of court because the claims made by the manufacturers of the original product were not substantiated by the facts, and although the competing manufacturer used labels so closely imitating the original as to deceive the public, yet the defendant had no status in court and lost the case.

It is our desire as a committee to impress upon the profession the necessity of conforming our methods as pharmacists and manufacturers of materia medica products with professional and scientific requirements, so that we may receive the endorsement and co-operation of the medical profession. While it is true that a large number of physicians are utterly indifferent on the subject, and do not care what course is pursued by the pharmaceutical profession and manufacturers, yet, medical scientists are quick to draw the line between the altruistic work of the medical profession and the commercial methods of those engaged in the materia-medica-supply business. One of the reasons why the medical profession is indifferent to the course pursued by pharmacists and manufacturers is because they consider us outside the pale of professional life, and therefore it is a matter of indifference to them what course we pursue. Let the physician patent his therapeutic inventions or surgical instruments and he is ostracized by the fraternity because he has violated the principles of fraternity and professionalism upon which medical practice is founded. But it is not expected by them that persons engaged in commerce will conduct their vocations in harmony with the beneficence and liberality which is supposed to characterize the medical

profession. If we wish to secure professional recognition we can only do so by becoming professional men.

The medical profession does not consider it contrary to professional usages for medical authors to associate themselves with publishing houses for the publication of copyrighted books, and it is probably true that there would be no objections to physicians associating themselves with pharmacists and manufacturers for the production of materia medica products protected by process patents and brand names provided the products themselves and their proper distinction or currently used names are left free for introduction to science by the way of the educational channels of the profession. But we cannot expect endorsement for any plan whereby the products themselves and their names are commercially controlled and the educational machinery of the profession converted into a great advertising bureau for the exploitation of alleged new remedies by advertising.

To Recapitulate: 1st. That products and names of products should be free so that the products themselves as to their course or genesis, physical and chemical properties, methods of preparation, preservation, compounding and dispensing, and methods of applying them in the treatment of the sick may be impartially discussed in the medical journals, societies and colleges without forcing those who discuss them to advertise any one's special make of products. This will protect the educational machinery of medicine and pharmacy and secure the co-operation of the medical and pharmaceutical professions in the introduction of the products to science, thereby popularizing them without expense to the manufacturers.

2nd. Brands of products and the names of the brands should be commercially controlled by the manufacturer; that the advertising should be directed to creating a demand for the brands; that the manufacturers or commercial introducers who spend their good money in advertising may be protected in their investments.

3rd. Advertisers should be forced to tell the truth in their advertising and not permitted to create a fictitious demand by misleading statements, thus injuring their competitors by acts of unfair competition in trade.

In conclusion, we wish to again call attention to the suggestions several times made in previous reports of this committee, and the Committee on National Legislation, regarding the advisability of establishing some kind of Board of Control representing the medical and pharmaceutical professions and manufacturers engaged in the legitimate pharmacal and chemical industries, the same to work in co-operation with the universities, medical schools and colleges, government laboratories, and Patent Office for the proper introduction of materia medica products to science and brands of the same to commerce, and the proper application of the patent and trademark laws to materia medica commerce.

One of the first subjects for such a Board of Control to take up would be that of materia medica nomenclature for the purpose of making rules to be adopted by the manufacturers who affiliate themselves with the Board. The rule in regard to nomenclature should be one to protect the manufacturers by having the Board coin generic names for each product manufactured under the censorship of the Board, thus protecting the commercial interests of the manufacturers and

introducers on the one hand, and materia medica science and the practitioners of the medical and pharmacal arts on the other.

The suggestions of Mr. Frank H. Freericks, of our committee, should also be considered. He recommends a conference between representatives from the different pharmaceutical associations similar to the National Drug Trade Conference which has been held with reference to Federal narcotic legislation. In order to bring such a conference about, or to have the matter considered by the existing National Drug Trade Conference, it was suggested by Mr. Freericks that the A. Ph. A. upon the recommendation of this committee, vote on the subject.

The special subjects offered for discussion are as follows:

1st. The suggestion that the A. Ph. A. memorialize Congress by asking for a repeal of that portion of the patent law which permits the patenting of materia medica products, or substances used in the treatment of the sick.

2nd. The compromise suggested by Mr. England regarding the suspension of product patents by the Commissioner when improved processes are devised for their production.

3rd. The advisability of establishing some kind of a Board of Control representing the medical and pharmaceutical professions, manufacturers, medical and pharmaceutical colleges, the press, and government laboratories for the adoption of proper rules in relation to the introduction of materia medica products to science and brands of the same to commerce; said Board of Control to work in co-operation with the Patent Office in an advisory capacity.

4th. An expression of the Association in regard to the proper application of the patent and trademark laws in relation to materia medica inventions.

5th. The suggestion of Mr. Freericks in regard to a special conference or consideration by the existing National Drug Trade Conference.

Respectfully submitted by the Committee:

S. L. HILTON,
W. BODEMANN,
F. H. FREERICKS,
J. W. ENGLAND,
F. E. STEWART, M. D., Chairman.

Section on Practical Pharmacy and Dispensing

Papers Presented at the Sixty-First Annual Convention

SOME ADDITIONAL SOURCES OF ERROR IN THE CHEMICAL EXAMINATION OF URINE.

JOSEPH L. MAYER, NEW YORK.

At the 1907 meeting of the Association I read a paper, "Some Sources of Error in the Chemical Examination of Urine" (Proc., 1907, page 486) in which attention was called to various factors which if not observed would lead to faulty findings in connection with analyses of urine; since that time other sources of error have presented themselves which are of sufficient importance to be offered now.

In testing for sugar Fehling's Solution has the disadvantage that too large an amount of urine is employed with the consequence that foreign substances very frequently interfere, therefore Haines' Solution which only employs 8 or 10 drops of urine is suggested to overcome this difficulty, but as I pointed out in another paper, (Merck's Report, June, 1905), this solution is not stable, but deposits red oxide of copper on standing without the presence of urine and for that reason it is not of much value.

Recently Benedict, (Druggists' Circular from Jour. Amer. Med. Ass'n, January, 1912), has suggested the use of a solution in which 8 drops of urine are employed and the keeping qualities of the solution are such that it will keep indefinitely.

The solution and urine must be heated a minute or two to obtain the best results, a reaction only being regarded as positive when the greenish tinge extends throughout the whole mixture. A test tube is very unsatisfactory to perform the test in, therefore I employ a very small Erlenmeyer flask into which 5 cc. of Benedict's solution is measured with a pipette, and then 8 drops of urine added from a medicine dropper and the whole placed on the hot plate, and when the material starts to boil it is timed for $1\frac{1}{2}$ minutes and then poured into a small test tube and allowed to cool spontaneously. It is a good plan to place a small funnel in the neck of the Erlenmeyer flask to act as a reflex condenser and prevent undue evaporation.

Where the quantity of sugar is large the presence of sugar is indicated at once by the green color whereas a small quantity of sugar is only revealed when the solution cools. If the mixture remains blue, sugar is absent.

For the quantitative estimation of sugar, Benedict's solution for quantitative work gives excellent results if properly employed. Benedict directs measuring the reagent into a porcelain evaporating dish, adding sodium carbonate, powdered pumice stone or talcum and boiling over a free flame.

This procedure did not yield very good results and I therefore altered it as follows:

Into a 100 cc. Erlenmeyer flask, with cord wrapped around the neck to prevent burning the fingers, measure with a pipette 25 cc. of Benedict's quantitative solution, add about 10 gram anhydrous sodium carbonate, a couple of pieces of pumice stone which have been heated to white heat and plunged into water, and about 10 cc. distilled water and place the whole on a hot plate until the solution boils and the sodium carbonate is dissolved, then begin adding the urine in small amounts from a burette, allowing sufficient time between each addition for the reaction to proceed, the end being indicated by the disappearance of the last trace of blue. As in the qualitative test it is a good plan to place a small funnel in the neck of the Erlenmeyer flask.

The use of the hot plate which I suggested in a paper read before the N. Y. S. Ph. Ass'n (Proc. N. Y. S. Ph. Ass'n, 1911, page 261) enables the qualitative and quantitative determinations to be carried out without any source of error.

Purdy's test for albumin using three-fourths of a test tube full of filtered urine, adding $1/6$ of the volume of saturated solution of sodium chloride, acidifying with acetic acid and heating the upper inch of the mixture is a very sensitive and trustworthy one, but care must be exercised to keep the tubes very clean for when they are in use some time the portion of the tube which is constantly heated assumes a milky appearance with the result that albumin is indicated where none should appear.

Testing for acetone by adding solution of sodium nitroprusside to the urine acidifying with glacial acetic acid and overlaying with ammonia water is a very good test, but if the urine contains phenolphthalein there will be produced a coloration very much the same as when acetone is present.

In testing for indican by adding hydrochloric acid and an oxidizing agent, it is well to remember that after large doses of codeine a purple-red color is frequently produced which may obscure the blue color. In addition, if the urine contains iodine, the chloroform portion of the test will be colored carmine and it becomes necessary to add solution of sodium thiosulphate to decolorize it when the blue color will be plainly seen, if present.

In testing for diacetic acid the fact must not be overlooked that it is very volatile and that tests must not be made after the sample is a day old. The test is made by adding ferric chloride solution to the sample when the phosphates are all precipitated; further addition of the reagent produces a deep reddish-brown color which also appears if salicylic acid, phenol, acetic acid and other substances, produced after taking various other drugs are present.

A better test is Liplawsky's modification of the Arnold reaction, which according to Wood (Wood's Chemical and Microscopical Diagnosis, page 553) is carried out as follows:

Two solutions are kept in stock. One is a 1% aqueous solution of para-amidoacetophenon with 2 cc. of strong hydrochloric acid in each 100 cc. of the mixture; the other is a 1% solution of potassium nitrite. To apply the test take 6 cc. of the first solution, 3 cc. of the second solution and 9 cc. of the urine to be tested. Add a drop of strong ammonia and then shake the whole thor-

oughly when a brick red color will appear. Ten drops to 2 cc. of the mixture of urine and reagent are then removed to another tube and 20 cc. of strong hydrochloric acid and 4 drops ferric chloride solution added, together with 3 cc. of chloroform. The corked test tube is then slowly tilted from side to side so as not to emulsify the chloroform. At the end of a minute, if diacetic acid is present, the chloroform will assume a violet color. In normal urines the color will be either a yellow or pale red. Salicylic acid and similar drugs do not interfere with the reaction.

In testing for bile with tincture iodine, the test to be successful must be made with a tincture of iodine diluted with alcohol until the color is a dark yellow which is applied by using a dropper to form a layer of reagent over the urine. A green ring indicates a positive reaction. Antipyrine yields the same reaction.

A better test is to take some of the suspected sample, add enough U. S. P. magnesia mixture to produce a precipitate and filter. When the material has filtered through, place the paper containing the precipitate on a white porcelain surface and add to it a drop of yellow nitric acid. A green color indicates bile.

These few notes like those published before are not intended as a course of instruction in uranalysis, but simply to point out some sources of error in the chemical examination of urine.

DISCUSSION.

Otto Raubenheimer, of Brooklyn, said he wished to call attention to two points in connection with this paper. One was, that Benedict's solution was not at all a new one. An attempt had been made to introduce Benedict's solution in the U. S. P., but it was declined with thanks.

R. H. Needham, of Ft. Worth, Tex., said that a good many authorities claimed that Haines' solution would keep indefinitely. His experience had not shown this to be true. Benedict's solution he had used for quite a while, and his experience had been that it kept well for two years. The last he had was four ounces in a five-pint bottle, which seemed to be just as sensitive at the end of that time as at the time he made it up.

CAMPHORATED OIL IN AMPOULES, SIMPLE APPARATUS FOR FILLING.

J. LEON LASCOFF, NEW YORK.

In 1909 Mr. Caswell A. Mayo read a very interesting paper before the New York Branch of the Association entitled: "Ampoules and Their Use in the Preservation of Sterile Solutions," in which he explained how easily the dispensing pharmacist can put up any sterile solution in ampoule form.

I was very much interested in this subject, and began experimenting, with the result that I met with marked success.

My object in selecting the subject of Camphorated Oil Ampoules, is that during my experience as a pharmacist I have had more calls for Camphorated Oil Ampoules than any other kind. In former years, when physicians prescribed camphorated oil for hypodermic use they had to be prepared extemporaneously,

which took a great deal of time and they were not always sterile. As such solutions are needed in emergency cases, the idea of making ampoules in sterilized form is far superior to the old way of preparing fresh ones every time they are required.

At the time my experiments began I had great difficulty in obtaining the empty ampoules, as they were not yet stocked generally in the United States. If the dispenser is only ordinarily skilled in glass blowing, he can make them himself from test tubes.

The chief consideration which I have had in mind was to devise a simple, non-expensive and practical method of filling glass ampoules with sterile camphorated oil. Sterile, because they are used by the physician in the hypodermic syringe and this had to be done without the use of too much heat as the camphor volatil-

APPARATUS FOR FILLING AMPOULES DEVISED BY J. LEON LASCOFF, NEW YORK CITY.

ized, so I devised the apparatus shown in the illustration. A single apparatus for making one dozen only may be used, but in cases where more than that number is required, a double apparatus may be used as shown in the diagram. It works very satisfactorily and in all cases the ampoules prove to be sterile, as I have in my possession the case reports in which they were dispensed. No infection has resulted from their use, either on the skin or in the deeper tissues. That the strength of the camphor was uniformly up to the standard has been testified to by the physician who prescribed and used them.

Having covered the technical side of the question, let us now turn to the commercial. We frequently see the statement made in print that professional pharmacy does not pay; that there is no money in prescription work. Let us take this particular preparation, ampoules of camphorated oil, and see whether they

have paid me or not. The permanent investment for the small outfit consists of the following:

SMALL OUTFIT.

1 Electric hot plate.....	\$5.00
1 Sterilizing oven, costing..... (Cake box, 80c; insulating cover, 75c.) (Fixing interior shelf, 25c.)	1.98
1 Test tube, 4x 2.....	.50
1 Ginger ale holder.....	.25
1 Perforated rubber stopper.....	.35
2 Bent glass tubes with ground glass stop cocks.....	2.40
Rubber tubing20
1 Metal syringe	2.25

Total permanent investment..... \$12.93

LARGE OUTFIT.

1 Wash bottle	\$0.25
2 Bent glass tubes.....	.20
1 Rubber stopper15
2 Glass cups, 2 x 5.....	1.00
2 Rubber stoppers, No. 11.....	.70
4 Glass tubes with stop-cocks.....	4.40
Rubber tubing40
Electric heater	5.00
Sterilizer	1.98
2 Ginger ale holders.....	.50
Air pumps	2.50

\$17.08

By using a Bunsen burner for sterilization instead of an electric stove and by using one instead of two glass stop-cocks, this can be cut almost a half, making the permanent investment \$5.53.

The cost of the ingredients for a 2 cc. ampoule of camphorated oil, and the ampoules amount to a little less than 15 cents a dozen. I had one prescription for six ampoules for which I charged 90 cents. This was refilled forty-one times, making the receipts \$36.90 from this one prescription alone. Another prescription called for twelve ampoules. For this I charged \$1.25. It was called for 150 times, making \$187.50 received from this prescription. The two prescriptions therefore brought in a total of \$224.40. From this deduct permanent investment of \$17.08 and the cost of the materials for 170-1/2 dozen at 15 cents a dozen, \$12.75, and we have a net profit of \$224.40—\$29.83=\$194.57, plus the apparatus. On an average the dispensing of the prescriptions required not more than 15 minutes of actual working time or a total of $191 \times 15 = 47\text{-}3/5$ hours. Allowing a dollar an hour as fair compensation for prescription work this leaves \$194.57—\$47.60=\$146.97 profit above the cost of investment, material and labor. I do not think that commercial pharmacy can make any such showing on any of its investments.

DISCUSSION.

C. A. Mayo, of New York, said that he had been very much interested in the subject of ampoules since it was first brought up before the New York Branch, and had presented quite a complete paper before the Association at Los Angeles, at the 1909 meeting. It had afforded him great pleasure to observe Mr. Lascoff's apparatus in his store. Not only did he see him

fill one of these prescriptions, but he had brought out the account, and he had figured out himself how much money he had gotten on two prescriptions. He had been impressed with the thought that this was one of the best answers to the statement that professional pharmacy did not pay—that on these two prescriptions alone a profit of over \$100 had been made. Mr. Mayo said it had afforded him great pleasure to testify to this particular phase of the matter. This work had been done in a rather small store, in a remodeled residence on a corner. The prescription room only measured some 12 by 15 feet, had no elaborate marble-tops in it, but was one of the most complete and neatest and cleanest places he had been in for a long time; and it had done his heart good to see a "real pharmacist." It was not only important that the pharmacist should make money, but he should know whether he was making it or not, and how he made it, if he did make it. The system of accounting in this case was so accurate and readily comprehended that one could find out in five minutes how this man had made his money.

H. A. B. Dunning, of Baltimore, said that a very simple process in use in his establishment for making camphorated ampoules was to simply fill the ampoule by the use of a subcutaneous syringe, seal the ampoules and place in an Arnold Sterilizer, sterilizing the ampoules and contents at the same time. Being sealed, no camphor could be lost. His apparatus only cost 75 cents.

LOTIO ALBA.

OTTO RAUBENHEIMER, PH. G., BROOKLYN, N. Y.

The prescription calls for Lotio Alba. In this age of white dress, white flag, white cross, white linen, white plague, white slavery and whitewashing, undoubtedly White Lotion, or White Wash, will be of interest to the pharmacist. However, he is at a loss as he is unable to find a formula for this preparation, even if he is equipped with a good sized pharmaceutical library. No pharmacopœia, no National Formulary, no other formulary, and no dispensatory, *the* book which is looked upon to give all kinds of pharmaceutical information, mentions Lotio Alba. Even such authorities as Remington, Caspari, Arny, Fenner, Hager, Dietrich, Buchheister, Hell, Dorvault, Orosi, MacEwan, Martindale and others, and such standard works as the British Pharmaceutical Codex, and the Pharmaceutical Journal Formulary do not mention Lotio Alba.

Upon getting in touch with the physician the pharmacist is informed that this preparation is used largely in hospital and dispensary practice. If the pharmacist is fortunate enough to possess a hospital formulary, as for instance, that of Bellevue and Allied Hospitals in New York City, then he at last finds a formula for Lotio Alba, or White Wash, which is composed of zinc oxide, solution of lead subacetate, glycerin and lime water. This however, is not the preparation which the physician intends to be used against acne, pimples, blackheads or other skin affections. Lotio Alba is composed of zinc sulphate, sulphurated potassa and water, or rose water.

The writer, as chairman of the Committee on the A. Ph. A. Recipe Book, is well aware of the fact how difficult it is to find a formula for Lotio Alba. It

is for this reason that in the July number of the Journal of the A. Ph. A., 1912, page 761, he has published the following formula:

LOTIO ALBA
White Lotion
Lotio Sulphurata

Zinc sulphate	5 gm.
Sulphurated potassa	5 gm.
Water, or Rose water, a sufficient quantity to make..	125 cc.

Dissolve each chemical in 60 cc. of water, or rose water, which latter is preferred by some dermatologists and also by some patients on account of its odor. Filter each solution and mix by slowly pouring the potassa solution into the zinc solution, then add sufficient water or rose water to make 125 cc.

If the pharmacist is a member of the A. Ph. A. and keeps or binds the Journal of the A. Ph. A., or if he is a reader of *The Practical Druggist*, he can find this formula in the Journal, as said before, or in *The Practical Druggist* for November, 1912, page 44. This prescription originally came from France and was introduced into the U. S. around the 70's and has been used extensively since, in fact its use in dermatology seems to be on the increase.

Potassa Sulphurata, Sulphurated Potassa or "Liver of Sulphur" was official in U. S. P. 1890, and must have been of some importance at that time, as it was admitted into the Appendix of the N. F. III, page 226, together with a formula for its preparation. There is a great difference in this substance in its physical characteristics, as well as its chemical composition. As can be seen from the specimens exhibited it varies from a dark liver-brown color to dark yellow, dark green, light green or even gray. When fresh it has a strong characteristic hydrogen sulphide odor which, however, upon exposure gradually decreases so that old "liver of sulphur" does not resemble liver or sulphur, being practically odorless and worthless. Owing to its rapid deterioration, it is absolutely necessary to keep it in well stoppered bottles, which is one of the specifications in the monograph of the National Formulary. Chemically, sulphurated potassa is a mixture of potassium trisulphide, K_2S_3 , and potassium thiosulphate, $K_2S_2O_3$. Sulphurated potassa when prepared according to the N. F. should be almost completely soluble in two parts of water. On account of the importance of this chemical and inasmuch as it will be readmitted into the U. S. P. IX, no doubt some one, if not the writer, will give us a paper on the history and chemistry of potassa sulphurata.

The value of White Lotion depends upon the strength of sulphurated potassa. If the latter is fresh and contains the proper amount of potassium polysulphides, then the solution of zinc sulphate will be decomposed into zinc sulphide, which is a white precipitate and which is desired by the prescribing physician and which is of value in the treatment of acne, etc.

Prescriptions calling for 2 oz. of Lotio Alba, containing 1 dram of each chemical, have been compounded in different pharmacies in New York, Brooklyn and elsewhere and samples of same are herewith submitted. For better comparison these specimens are put in uniform bottles.

The color of these lotions varies from a pure white to gray or brown, some of them being so dark so as to deserve the title "Black Lotion." As to the precipitate this ranges from a very coarse to a very fine texture. Some precipitates are very dense, others are very bulky. In fact one sample is colorless like water, evidently having been filtered in order to improve (?) its appearance! This wide variation most certainly deserves the careful attention which pharmacists must pay to the preparation of Lotio Alba.

In the formula for Lotio Alba given above the writer has taken the pains to specify the proper manipulation. The following should be borne in mind:

- I. The zinc sulphate solution should be filtered, if necessary.
- II. The potassa sulphurata employed must be fresh and must possess a strong H_2S odor.
- III. It is absolutely necessary to filter the sulphurated potassa solution, to remove any insoluble portion, which would act as an irritant to an inflamed skin.
- IV. In order to obtain a finely divided precipitate it is necessary to have both solutions as much diluted as possible.
- V. According to the experience of the writer and other prominent pharmacists it is best to *slowly* pour the potassa solution with constant agitation into the zinc solution. By this method a more bulky precipitate is obtained, which is the desideratum of the prescriber.
- VI. The lotion should be dispensed with a "shake well" label.

As stated above, the author, as chairman of the Committee of the A. Ph. A. Recipe Book has proposed a formula containing 5 gm. each of zinc sulphate and sulphurated potassa in 125 cc. of water. Dermatologists all over the country prescribe this lotion in different strengths, generally varying from 1 to 2 drams of each chemical in 4 oz. of water or rose water.

Sulphurated potassa is a mixture of polysulphides, potassium thiosulphate and potassium sulphate. The best variety, that is one which has not been overheated, contains potassium trisulphide. According to its approximate molecular weight, 354.23 gm. of sulphurated potassa contains 169.21 gm. K_2S_3 and 185.02 gm. $\text{K}_2\text{S}_2\text{O}_3$. In the preparation of Lotio Alba the following change takes place.

From this chemical equation it can readily be seen that in Lotio Alba, containing equal parts of the chemicals, all of the sulphuret is decomposed, in fact that there is an excess of zinc sulphate. This accounts for the fact that there is no odor of hydrogen sulphide in the finished lotion if properly prepared. The precipitated sulphur is, of course, in a finely divided state, just what is desired by the dermatologist.

As explained above sulphurated potassa is very unstable. What is the average pharmacist going to do when he receives an occasional prescription for Lotio Alba? There are two ways to overcome this difficulty.

I. Preparing small quantities of sulphurated potassa by the pharmacist himself. Although this might seem an odoriferous manipulation, it can easily be accomplished, especially under a flue or in the open air, and the writer himself has done so on numerous occasions with but very little trouble.

II. The preparation of a solution of fresh sulphurated potassa in water. Strange to say, *the solution* of this unstable chemical is *very stable* and the writer takes pleasure in exhibiting specimens which are one and two years old respectively. The chemical is almost completely soluble in two parts of water, but for convenience the author is in the habit of keeping in stock a solution four volumes of which represents one part of potassa sulphurata. The preparation and keeping of such a stock solution for the quick and proper preparation of Lotio Alba has been kept quite a secret, a so-called professional secret, by the pharmacists who are favored with the prescriptions of dermatologists. The writer, who believes in the motto, "To give and take pharmaceutical knowledge," takes pleasure in herewith presenting this "secret" method for the benefit of his brother pharmacists.

DISCUSSION.

In reply to a question by Mr. Fennell, as to whether, in these dark preparations, the zinc sulphate contained any iron, Mr. Raubenheimer replied that the black color was probably due to the presence of ferrous sulphide. The sulphurated potassa contained iron due to the fact that the manufacturer made it on a large and cheap scale. He merely melted his potassium carbonate and sulphur together and poured it out into an iron tray, and it would be noticed in one of the samples passed around that it was yellow on one side, and on the other side was black. Without filtering the solution, a gray precipitate would be had. He had filtered it, with the result as shown.

H. A. B. Dunning, of Baltimore, said that in his establishment they used much the same method as Mr. Raubenheimer had outlined for preparing solution of sulphurated potash. To insure the strength of the sulphide solution, they selected that portion of the sulphide which was yellow. He had found it necessary to keep the substance tightly stoppered, otherwise there was more or less change in the condition of the sulphide. It seemed remarkable that there were in the United States, in any of the cities from which these samples came, concerns that would send out such products as were to be seen on the table before the members. He thought it was not expressing it in language too strong to say that it was a disgrace that this should be true.

Mr. Raubenheimer stated that these samples came from all parts of the country, some from New York, some from Brooklyn, and some from Philadelphia; but none had come from Baltimore, nor had any come from Cincinnati.

A PRESCRIPTION AND A QUERY.

A. W. BENDER, DETROIT.

The following prescription was compounded by a local pharmacist:

R Atropinae sulphat004
Argenti nitrat1
Bismuth subnitrat	5.
Magnesii oxid	5.

M. et div. in pulv. No. XV.

Sig.—One powder after meals and one an hour later.

During the first day six powders were taken according to directions and no ill effects were experienced. On the second day after having taken two powders in the morning, the patient began to feel dizzy and noticed that the pupils of his eyes were greatly dilated. An overdose of atropine was suspected and he stopped

taking the powders, but during the remainder of that day found it very difficult to read or to use his eyes in any way.

The following day the prescription was compounded in this laboratory using an analytical balance, sensitive to 1/600 grain, to weigh out the ingredients. After resting a day the ill effects experienced from the powders put up by the local pharmacist had entirely passed away and the patient began taking the new powders. He took them for a week according to directions and they caused no ill effects.

The difference in the action of the powders led to an investigation. Mr. W. M. Jenkins of this laboratory, who is thoroughly familiar with alkaloidal assays, analyzed the powders and found 1/100 grain Atropine Sulphate in each powder instead of approximately 1/250 grain which the prescription called for. This showed that the patient was getting the maximum dose of atropine sulphate instead of the prescribed minimum dose.

The facts in the case were presented to the pharmacist and inquiry was made as to the method used in compounding the prescription. It was found that he had weighed 1/16 grain atropine sulphate on a Torsion balance and had rubbed it up with the other ingredients. He stated that it had always been his practice to weigh out such small amounts on this balance and he believed it to be sensitive to this amount. After a short discussion he decided that thereafter he would use Dispensary Tablets or Tablet Triturates, in a prescription of this kind.

What is the correct way to compound this prescription providing there is no analytical balance at hand? Ought a pharmacist to have an analytical balance?

SCIENTIFIC LABORATORY, PARKE, DAVIS & Co., Detroit, Mich.

DISCUSSION.

G. F. Payne, of Atlanta, said he had occasion to use the prescription balance a great deal, as he had found it out of the question to use the analytical balance in many cases. It was too delicate, and had to be adjusted each time it was used. To weigh out whatever quantity the balance was accurate for, and then divide it very carefully by the eye, would be found to be a very accurate method when done properly.

C. T. P. Fennell, of Cincinnati, thought there was no trouble with the balances on the market, but where pharmacists did make a great mistake was, that they would shove their balances around from one place to another, and did not keep them properly leveled.

W. C. Alpers, of New York, thought the analytical balance should not be used in the drug store, as it required too much adjusting. It took a great deal of experience to weigh accurately upon it, and it was not expected of the average pharmacist that he should have the deftness to be able to handle it.

I. A. Becker, of Chicago, said he would like to bear testimony to the various weighings that could be made on a scale by not having it perfectly level. He had found that the ordinary box prescription scale, not furnished with a leveling device, would not do on the prescription counter, as its sensibility was very much affected by its being out of level.

NECESSARY APPARATUS IN A RETAIL PHARMACY.

JEANNOT HOSTMANN, HOBOKEN, N. J.

The subject of this paper has been discussed so often from its many sides in recent years, that it may seem a wasted effort to spend any further time in bringing it before this Association.

Agreeable to Mr. Lascoff's request, I will limit myself as much as possible to the chemical side of the question, he having made this suggestion knowing that I spent fifteen years in the retail drug business previous to my connection with the Department of Chemistry of the New York College of Pharmacy.

Having had considerable experience in testing and assaying prescriptions that had been compounded in New York City and Newark, as well as ordinary everyday counter samples, the writer believes that, although there exists, and always will exist, many cases of wilful adulteration and sophistication, that many a pharmacist who is hauled over the coals by Boards of Pharmacy, Health, Food Commissioners, and newspapers, is guilty only so far in that he has been lacking in giving the proper care to the kind of drugs he is purchasing as well as neglecting absolutely to convince himself that what he purchases is really up to the official requirements. It may seem very radical to suggest that every pharmacy should have as an adjunct to an up to date Prescription Department, a complete set of chemical apparatus, such as is necessary to perform the simpler tests and assay methods of the U. S. P., but the writer can see no other way in which the real pharmacist can protect himself from unnecessary trouble and expense except by not only making such installation as well as employing it faithfully and continuously.

It may be easier to buy from responsible firms and simply take their guarantee as being all that is required but this, at the best, is risky. Only recently, the writer in using some hydrogen peroxide sold by a firm possessing the highest reputation, discovered that it contained a considerable amount of barium; in another case, a sample of alcohol, labeled U. S. P. not only responded very vigorously to the aldehyde test, but also contained 10.5% of water. These examples prove conclusively that it is imperative that the pharmacist must protect himself and the only way he can do this is by being in a position to make the simpler tests himself.

The initial expense will not be very large, and will repay the owner many times in a short space of time.

I take it for granted that every pharmacy ought to be equipped with a real prescription balance in good order as well as accurate weights and graduates. The lack of these is the cause of much trouble. Impossible as it may seem, many pharmacists in a penny-wise-pound-foolish policy, purchase cheaply, never regarding quality. I have come across weights as much as 15% out of the way, and graduates run still worse. This is uncalled for as standard graduates can now be secured at very reasonable prices.

The above are necessary parts of a prescription department and as far as the

necessary chemical utensils are concerned, they will not take up very much space nor will the cost be prohibitive. I will mention a few that I consider absolutely necessary:

A rack of test tubes, a bunsen burner, a small assortment of beaker glasses and evaporating dishes, a water bath, some separatory funnels of various sizes, two burettes, a small assortment of pipettes, a set of metric weights from one milligram up and a balance sensitive thereto, test paper as well as the indicators employed in official methods. The U. S. P. list of reagents is very complete and the majority require no more than usual care in their preparation; for the making of volumetric solutions a few measuring flasks are absolutely needed. The majority of the reagents are fairly stable and if made up in small quantities, the more or less unstable ones will last the required time if conscientiously used. Of course, if they are prepared and placed upon the shelf and not made use of, they will naturally deteriorate and become useless.

With some glass tubing of various bores, a file, a cork-borer and some rubber stoppers, many pieces of apparatus can be prepared in short time and with little expense. An assortment of chemical flasks of various sizes is as necessary from a pharmaceutical as a chemical standpoint. A few crucibles—porcelain is adapted for most work—are also necessary as well as supports for same. A microscope magnifying to at least 350 or 500 diameters I consider absolutely essential, not so much for chemical as for pharmacognostical purposes.

Some few small glass funnels and small filters, particularly some of the quantitative kind, should be at hand.

The determination of specific gravity of many substances is of such very great importance that the necessary apparatus must be at hand. The principal one of course is the pycnometer or specific gravity bottle.

The specific gravity and solubility of substances being determined at certain stated temperatures, one or two accurate chemical thermometers must be at the worker's disposal.

I think that the above list covers the most important and needed pieces of apparatus although undoubtedly some have been forgotten.

Considering the time spent in getting the methods of tests of identity and for impurity and strength, as well as the assay methods for galenicals, given in the Pharmacopœia in such splendid working shape specially adapted to the pharmacist and also considering the high class and thorough education received by students in the better class of colleges of pharmacy to-day fitting him particularly for such work, it seems almost a crime that so few pharmacists are making proper use of the knowledge at their disposal in such a way that could not but raise their professional standing as well as increase the financial returns of their business.

In view of the fact that there is a continuous discussion being carried on as to whether pharmacy is going backward or forward, it appears to the writer, that there are many pharmacists scattered throughout our country who are making not only an enviable, country-wide reputation, but also getting large monetary returns from the professional side of pharmacy as practiced by them as real pharmacists, principally by employing the highly scientific knowledge at the disposal of every pharmacist who chooses to make use of it.

The writer's ideas will probably be regarded by many as radical, but he thinks that in the very near future it will become necessary to compel the pharmacist to have the proper chemical apparatus essential to carrying out the tests and assays mentioned above, just as it is now compulsory by law in certain states, that every pharmacy possess a U. S. P. and N. F. When this time arrives and the pharmacists perform the necessary work, we will hear much less about saturated solutions being deficient in strength, and many other cases now quoted, showing or trying to show the offending pharmacist as a law breaker and offender, in many cases unknowingly, will disappear.

COLUMBIA UNIVERSITY COLLEGE OF PHARMACY, August 15, 1913.

DISCUSSION.

Otto Raubenheimer said it seemed a pity that, after a pharmacist had received his training in a college, and in chemical and analytical work, he should forget all about it, and should not any more handle burettes or pipettes, but devote himself to the commercial end of the business. How much more profitable it was to devote a little time in the store to the professional study of the business, and do a little analytical work, especially as, when once commenced, he would come to like it. Another object, after the wholesaler once came to know that the pharmacist kept track of him, he would send him the best he had. He would not advise anyone to keep his chemical apparatus in the back of the store, but it should be kept in front.

F. W. Nitardy, of Denver, said his experience had been that, whereas the jobbers did not at first carry such things as U. S. P. alcohol, turpentine and linseed oil, they were now obtainable, as the result of shipping back a few things not of standard quality.

SELLING AN ANTISEPTIC.

Every household ought to have a harmless antiseptic on hand for emergency use, and every druggist ought to have the same on sale as a leader and business builder. In this day of wide information, everybody knows about germs, and a great many people believe in being prepared. These people will buy your antiseptic without any urging on your part. All you have to do is to put the stuff on display. Other people may be easily educated into keeping an antiseptic constantly on hand. If they don't know, teach them. You are doing them a good turn and building business for yourself.

A POUND OF PREVENTION
MAY BE WORTH A TON OF CURE.

Such is the sign one enterprising druggist has posted over a pyramid of pound bottles containing a harmless and popular antiseptic. His reading matter explains how an antiseptic applied in time renders a cut or wound aseptic, hastens the process of healing, may prevent lockjaw, and so on. This simple arrangement increased his sales over 500 percent. This is the way to build business. Help the community, and at the same time build business for yourself.—W. S. Adkins in *The National Druggist*.

Papers Presented to Local Branches

EFFICIENCY IN THE DRUG STORE.*

A. K. LOBECK, PHILADELPHIA.

The word efficiency comes from the same Latin root from which the word *effect* is derived, a root meaning *to make* or *to do*. The accepted definition of the words efficient or efficiency comprises the causing of *effects* or the producing of *results*. Let us hold on to this idea so that as we proceed deeper into the subject we will have something to which we can return when we go astray.

The owner of a drug store, to be efficient has two ends to accomplish. He must serve his customers with the best goods for the lowest prices possible, and he must make money for himself.

When we focus our eyes on the proprietor of a store we discover several factors with which he has to deal. Reduced to simplicity these are the factors: himself, as a personality; his clerks and other help; his stock in trade, store and utensils; and finally his customers. The efficiency of his whole business depends on how he controls these four factors, i. e., how he manages himself, his help, his stock, and his customers.

Himself. The proprietor of a business must be *interested* in it. That sounds like a very commonplace remark but, unfortunately, there is reason for it, for there are too many listless, uninterested men in business to-day.

When a proprietor feels that his interest is waning, there is nothing in the world will wake him up or invigorate him so much as an attempt to study his business with the view of making it more efficient. Of course it seems very illogical to expect a man who has fallen into such despondent and sluggish condition, which borders on despair, to turn in a moment and take the supreme interest in things which a study into efficiency demands. But, just the same, that is exactly what I say should occur. It is like a religious revival. And there is a psychological reason for it too. Professor James, the great psychologist, has said that it is indispensable, when a person is going to break off a bad habit, that he should adopt a new one in the most vigorous way possible, so as to destroy the old channels of thought.

The reason I bring up the question of the proprietor first is because I am sure that if the proprietor is not vitally, enthusiastically, and constructively interested in his business the end sought for will not be reached.

The Help. Shall we class the help with the cash register, the soda fountain, the mortars and pestles and the bottles on the shelves? Isn't the help part of the machinery of the store? You start at the suggestion but I am quite con-

* Read before the Philadelphia Branch, January, 1914.

vinced that every one of you is so classifying help in actual practice. You rent your store for so much a month; the interest on your investment for stock and fixtures is so much a month; you pay your clerk so much a month; apparently there is no difference. When I urge now that a clerk, and even a janitor, should be paid a regular salary and then a bonus depending on profits, many of you will say that it is all very well with some stores but not with yours. Do you know that that is just the cry that everybody puts up when improvements are suggested? We all think that the principles of scientific management are all very good in the case of other people but that we are an exception, or that we have peculiar conditions which have to be overcome some other way.

Another reason why we are unwilling to pay a clerk a bonus on the profits of the store is, not because we are stingy, but because we do not know what the profits are. We have no basis upon which to figure a bonus.

This plan is not proposed in order that the clerk will receive more money, but that he will know his income depends upon the success of the business, so that his whole attitude toward the business will be changed. Instead of being classed with the stock in trade and the machinery of the store, he joins hands with the proprietor as an active co-worker. It is a change in his attitude of mind which is greatly to be desired.

Then there is something else about the help which is even more important than how he is paid, and that is, what his responsibilities are. Every man in the store should know definitely where his duties begin and where they end. There should be an understanding so that everyone can work in unison. Unless there is an exact division of labor some things are certain to be neglected and the proprietor usually blames such neglect upon the nearest clerk. When there is a proper distribution of the responsibility, it does not mean that one man can not do another man's work when necessary, but it means that there is a basis for discipline. One man says, "Discipline is the keynote for the highest efficiency. Have each man's duties mapped out for him." No matter how small the establishment, this is vital.

The Stock in Hand, i. e., the Machinery of the Business. One of the most important parts of the machinery of the business is the money. The money that goes in and out of the business stands on just the same plane as the drugs and medicines which go in and out of the business. The money that is on hand stands on the same plane as the drugs which are on hand. The only difference between the two is that money is a universal medium of exchange while the drugs are not. It is handier to have money than it is to have a stock of drugs. But money is really quite in the same category with all other commodities. This is a basic economic principle.

The point, then, is that the druggist has a certain stock of business machinery on hand, among which is money. This business machinery he has to handle, manage and care for in various ways. In general these things all have to be cared for in the same way, as for instance keeping records of the amounts on hand, and keeping safely what is on hand, but specifically different methods are used to attain these ends.

Money being the most important of these commodities, simply because it is a universal medium of exchange and on account of this fact being the *meter* by

which the business man knows whether his business is producing results or not, it is essential that its records be kept with the greatest care.

This is ordinarily done by a device known as bookkeeping. Bookkeeping may be exceedingly complex or very simple, depending on the facts which are desired and the nature of the business. The ultimate fact which the druggist desires to know is what the net profit on his business is for a given period of time. But while this one fact is being learned a great many facts in the form of by-products may be produced. Some of these, for instance, are:

1. Amount of profit or loss every month on a given line of goods.
2. Percent of profit or loss on the investment for the different lines of goods showing which is really the most profitable.
3. Proportionate cost of handling different lines of goods based on rent of floor space, etc.
4. Distribution of the sales throughout the season, week, or day, giving a basis for the employment and relief of help.
5. Record of purchases of various lines of stock, giving data which will show whether it pays to buy in quantity or not.

Have you ever heard the expression that "a druggist can not see farther than the cash register"? I have that statement from an efficiency expert who has that belief because he knows very well that many of them are quite satisfied if they know what comes in each day and what goes out each day or simply if they know whether they are gaining or not.

Isn't it true that there are some proprietors whose pockets are simply an extension of the cash register drawer? The man who fails to appreciate the fact that his business is an organic entity which deserves to have an account by itself, is the kind of a man who doesn't know whether he is making money or not, and there are many of these.

There is another reason why the druggist should keep a rather accurate account of things. Every day the druggist is in business means so much valuable experience for him. And he is paying for this experience too. Should he fail to make it useful to him by not keeping a record of what is happening? The principle is the same as the case of a salesman who is on the road for a large firm. Everything he does he has to record, and all of these records are sent back to the home office to be sorted over, arranged and systematized to form the backbone for the firm's policy.

It may seem to be out of the question for the druggist to engage in a detailed system of bookkeeping. However, this is what he should do, and this is about the minimum.

He should have:

1. A columnar cash book in a handy place all the time in which are entered each day, from the cash register slips, on the left-hand side in the proper column the receipts from each line of goods, and on the right-hand side, in suitable columns, the amounts paid for salaries, for supplies, for each line of goods separately, and for miscellaneous and petty expenses.

Very little effort is needed to keep the cash slips entered up to date. The principle of the operation consists simply in sorting out the income into several incomes, and in sorting out the amount which is paid, into the several accounts corresponding to the incomes.

In a store doing more or less of a merchandise business the columns on the left side of the cash book would be something as follows: Proprietaries, Drugs, Cigars, Candies, Stationery, Prescriptions, etc. On the right hand side of the book would be similar columns so that when the columns on the right are totaled and subtracted from the totals of the respective columns on the left plus the inventories, the differences will equal the profit on the different lines of goods, from which should finally be deducted the right proportion of the overhead charges such as rent, to obtain the net profits.

Whether there are several cash registers in the store, whether there is only one with several keys, or whether there are none, this system of cash book can be readily adapted to the business. Moreover, as the business changes and new lines of goods are taken up or old ones subdivided, new columns can be added.

2. A second book which the druggist needs is his check book. When he makes out checks, he transfers the amounts from the stubs to the proper columns on the right-hand side of the cash book. When he deposits cash on hand in the bank he makes no record in the cash book, whatever, but he keeps a record in the check book. However, before he deposits a check which comes in he must be sure to record it properly in the appropriate column on the left side of the cash book. The difference between the listed deposits in the check book and the checks drawn equals the bank balance. The difference between the two sides of the cash book (when the left exceeds the right) equals the cash balance. The difference between the cash balance and the bank balance equals the cash on hand in the cash drawer.

At intervals the bank pass book should be balanced at the bank and the check book should be reconciled to it. Thus the indicated bank balance in the check book plus the amounts of checks not returned by the bank equals the bank balance shown in the bank pass book.

3. When the store does a credit business a third book is needed. This is the ledger of accounts of customers. The simplest and most effective form of this which I have seen, is handled as follows:

When an account prescription is filled the prescription blank is stamped with a numbering machine and placed on a file. In the same way when a credit customer gets other articles in the store, a charge record is made out on a simple pad, this being kept usually in the cash register drawer (or it can be written directly upon the bill with the duplicate sheet beneath). Every week or so the prescriptions and charge slips are entered on bills. The bill head is made in a duplicate form which is folded over so that a carbon paper may be placed between the two sheets. With the typewriter the various items are entered upon the bill, the prescriptions by number only. The lower sheet which is therefore an exact duplicate of the bill, forms a page for a loose leaf ledger. When the upper sheet is sent as a bill to the customer the lower sheet is torn off and inserted in the ledger. When the bill is paid it is stamped so, and at the same time the corresponding page in the ledger is so stamped. Moreover, when a bill is paid the various amounts are entered in the left side of the cash book in their proper columns.

These three books constitute all the bookkeeping necessary but there is an additional device which is important. It is an order book. The order book is kept in a definite and convenient place. As soon as it is noted that an article is needed it is entered upon the book in the first column. There are several other columns so that when the article is ordered, opposite the original entry in the other columns, are entered the initial of the firm, the date, the quantity ordered, price, etc. Then, when the goods arrive, they may be checked.

When the bills come in from the wholesale houses, they can be checked either from the goods or from the order books already checked. The bills until paid should then be kept together in a folder with memoranda of all other items which require payment for which bills may not come to hand. This folder represents then the liabilities of the firm, in the same way that the account ledger represents the resources, and these two lists should be taken into consideration when profits and losses are being figured. When the bills are paid they are removed from this folder and the various items making up the bill are distributed in the proper columns on the right side of the cash book.

While some of these phases of the accounting may seem complex, it is all really simple and very readily done without consuming much time and with a very small chance of error. Practically all of the desired facts are readily available when wanted; profits on any line of goods can be figured in a very short space of time, and the cash account is always in a form so that it can be checked with both the cash drawer and the bank balance.

A good feature of such a system is that as much as possible is kept in the original entry.

This concludes that part of our discussion which has to do with the taking care of the money. The next problem is the taking care of the other commodities in the store, and in the handling of these commodities. Let us go to the prescription counter first. The following are some of the things that have to be taken care of here and arranged so that they can be found readily: poisons, chemicals, proprietary chemicals, tablets, tinctures, pills, clear and colored bottles, corks, vials, pill and powder boxes and other small containers, capsules and caps, all of varied sizes.

The poisons, chemicals, etc., should each have a special compartment and should be arranged alphabetically therein. There are certain difficulties in this connection and one of the greatest of these is the fact that these chemicals, etc., are kept in their original containers, and that these containers vary so in size and shape that a lot of shelf room would be wasted if a strict order were adhered to. This same difficulty arises in the stock room of every line of business and is overcome by the employment of the following principle: When there is a miscellaneous stock of various sizes which it is desired to keep in a uniform way it is necessary to divide the storage space into units which will accommodate the largest class of the articles to be stored and then subdivide the units to suit the sizes of the smaller articles as they are interspersed among the large ones. The particular device which suits the drug business looks like a filing cabinet, in which the compartments are of the same size and shape. When one of the compartments is pulled out and looked at from the side it is seen to have adjustable shelves running across it so that a large bottle can be stored with small ones and in a minimum of space. This device is supreme over all other methods and is almost indispensable where space is limited.

Very often some of these chemicals, etc., are bought in a rather large quantity and transferred to small shelf bottles to be kept in the cabinet while the main quantity is stored away. In such cases it is suggested that on the front of the cabinet where the contents are listed some distinguishing mark be placed after or before the word to indicate that there is a quantity of this in stock elsewhere.

Where the expense prohibits the installing of such a filing system and where an improvement over the ordinary cabinet is desired, a very effective cabinet is one which has double or even triple doors provided with shelves. The conservation of space by means of such a cabinet is remarkable. In such a cabinet the different doors are used, one for poisons, one or more for chemicals, etc.

In case the unit filing system is in use, lists of the contents are attached to the outside of each division, of course in alphabetical order, and each class of articles relegated to its own sections, this arrangement being designated by large conspicuous labels. When ordinary cabinets are used, the alphabetical order is preserved but it is frequently convenient to have in addition, in each cabinet, a little stock list indicating the exact location of stock on the shelves. In the best stores that I have visited this was done.

The bottles, corks, vials, pill boxes, etc., are conveniently stored in drawers, beneath the prescription counter, these being divided into suitable compartments. It is essential that these drawers be labeled conspicuously on the outside. Capsules, caps, etc., are usually placed in drawers, above the counter, which should be accurately labeled. At the end of the prescription counter nearest to the store, should be the typewriter and beneath the typewriter a drawer for labels and paste. Many little details in arrangement suggest themselves here but any man who is on the lookout for efficient methods will devise just as good ones for himself. For instance, the caps and corks are kept near this end of the counter. Just beneath the ball or box from which the red cord hangs which is used for tying up the caps, there is kept attached to the counter, a stout piece of cord which is wound around and pulled tightly on the cap just after placing it on the bottle, thus giving it a good permanent crease which it retains when the more delicate red cord is applied.

When a prescription is filled this is about the routine to be followed:

First. Hang the prescription in a clip right in front of the counter where the dispenser can see it all the time.

Second. Take from the shelves the bottles of chemicals, etc., needed for the prescription and stand them in line at the right of the center of the counter.

Third. Weigh out each ingredient in order and incorporate it in the prescription, at the same time placing each bottle, immediately after weighing, to the left of the scales together with the weights which were used. By placing the used bottles at the left, one is sure that the ingredients on the left are in the mixture and those on the right are not in the mixture.

Fourth. Upon the completion of the prescription, have the ingredients and their weights checked, preferably by another individual.

Fifth. Label the bottle and wrap it up.

Sixth. Return the bottles to their proper shelves. This is facilitated and mistakes avoided if each class of bottle is designated by a certain bright-colored sticker which is placed on every bottle of that class. For instance, every poison bottle might have a red sticker, every chemical bottle a green one, every tincture bottle a yellow one, etc.

Seventh. File the prescription away. The ordinary method, of course, is the wire file. This has many objections, but it has some decided advantages. The advantage this method has over pasting into a book, is that, not only is time saved, but memoranda can be made on the backs of prescriptions, which is often done. Then, of course, books take up more room. The method of

filing prescriptions in sliding drawers has the advantage of keeping them neater, but they are less available, it seems to me, and it takes up a little more room and is more expensive. The best stores I visited in several cases still retain the old style long wire file with one or two minor improvements, and I admit its superiority.

Eighth. Wash up the pestle and mortar, graduates and other dishes instead of standing them around in the sink.

In connection with the prescription counter it is almost essential to have a list of the usual customers of the store with addresses and a mark indicating C. O. D. or O. K. for charge, so that when the messenger delivers the articles he has at the same time instructions as to whether collections must be made. Usually back of the prescription counter, there is a shelf reserved for books such as Pharmacopœias and Dispensatories, and if space is available also for current pharmaceutical literature. There is also a definite place, either a drawer or shelf, for catalogues of wholesale houses. In one store I visited almost half the space on the prescription counter was filled with a pile of miscellaneous journals and pamphlets, many still unopened; this to the great discomfort of the clerk who was at that time filling a prescription.

The criterion which shows whether a store is well arranged or not is the time and trouble that is required of a new clerk to find the things he needs.

Inspection of the cellars of several stores developed much of interest. The cellar is usually the stock room, and the ideal stock room, as intimated before, is divided into uniform sized units, which are subdivided to meet necessary requirements. The advantage of this, as mentioned before, is that it enables one to adopt any method of arrangement he desires, regardless of the size of the articles. He can arrange proprietaries together, or all the products of one firm together, or he can divide the stock into classes and arrange each class alphabetically. The division into unit compartments lends itself to any method of subdivision. The compartments are numbered and a stock-index of the goods refers to the unit compartment only, so that slight variations and adjustments are always possible without spoiling the system. No store visited, utilized the possibilities of this arrangement to the fullest extent.

In most stores inspected, the cellar was dirty and the stock subject to more or less dust. A very simple contrivance to prevent this, now in only very limited use, was suggested to me by a student who found it more than satisfactory. It consists in placing rolling window shades in front of the stock shelves. One roller is placed near the ceiling, the shade rolling about half way to the floor, at which point another roller is placed reaching the remaining distance. At the edges of the shades are nailed strips of wood behind which the edge of the shade passes. This keeps the shade close up against the shelves, and prevents the entrance of dust.

As soon as goods come into stock it is well to price-mark them immediately, as they are unpacked, and at the same time the wholesaler's bill should be checked.

In the main part of the store a strict logical arrangement of things cannot always be adhered to because display is often essential. The usual arrangement is that which tends to keep articles most in demand near at hand, and in many cases already wrapped or put up in small packages. Patent medicines are classi-

fied, with cough syrups together, liniments together, and so on. Wrapping paper cut in several sizes and kept in handy compartments just under the counter, saves time during the busy part of the day, and the use of elastic bands to snap around small packages adds materially to the speed of serving customers, but, owing to expense, should be used only during rush hours.

A drawer of labels similar to those in the prescription room should be kept in the front store, also corks and bottles. Many stores have auxiliary devices to help the clerk. For instance a stamp-vending machine saves much annoyance and I have assurance that it pays for itself.

In a large store the general arrangement is important. For instance, the aisles between counters should be opposite each other to facilitate the movements of clerks.

The Customers.—The final problem which confronts the manager of a store is his relation to the public. In this is comprised advertising, window dressing, etc., the details of which will not be considered here.

In closing I will summarize:

First of all, the proprietor himself must be interested in maintaining a standard. He must keep himself keyed-up by visiting other stores, by meeting other men, and by reading periodicals relating to his business.

Second, the proprietor must organize the work of the store so that all employees know exactly the extent of their duties and for what things they are responsible, and he must see to it that all including himself, have suitable hours for rest and recreation.

Third, he must look after the machinery of his business, including money and stock in trade, with an eye to the conservation of movements and time. He must have suitable arrangements for perfect cleanliness and order.

Fourth, he must study his customers.

After this exposition some of you may be reminded of the incident at the War Department at Washington just prior to the Spanish-American War. For several years the whole system was pervaded with an inordinate desire to get things in the most systematic condition possible in preparation for that event, and perfection was almost realized in every branch of the organization. During the war one of the clerks was heard to remark, "Oh, dear, I had this office in such fine shape, and then along came the war and upset everything." Evidently he had the idea that the war was an unjustified interruption of the work of the War Department. It may occur to some of you that after the store is systematized a rush of customers will come and upset the whole system. Therefore as a final suggestion let me add—organize the store while it is in action, so that every new arrangement will be put to an immediate practical test.

I stop now with the remark of a student: "Efficiency saves time and money, and the spirit of efficiency is the knowledge that one has trained himself to do all things well. It is full of inspiration to any worker. Being armed with that spirit he does his daily work better and looks beyond his daily work to further and to greater things."

STANDARDIZATION OF VOLUMETRIC ACID AND ALKALI SOLUTIONS.*

JOSEPH L. MAYER.

The U. S. P. VIII recognizes but one substance for the standardization of volumetric acid and alkali solutions—potassium bitartrate. This salt after being purified, as per directions of the Pharmacopœia, is employed to standardize the alkali, which then serves to standardize the acid.

This method is a very good one and leaves little to be desired with reference to accuracy.

Notwithstanding this fact, we constantly hear complaints concerning the method, mainly due to the time and trouble necessary to properly prepare the bitartrate, with the result that many students and pharmacists are inclined to employ some other method of standardization.

To determine the relative accuracy of other commonly used methods as compared with the pharmacopœial one the following work was undertaken.

The Bitartrate Method was employed by following the directions on page 532 of U. S. P. VIII for the purification of the salt and the method for standardizing V.S. KOH on page 552.

The H_2SO_4 V.S. was standardized by measuring 25 cc. into a 100 cc. Erlenmeyer flask and titrating in boiling solution with the above KOH solution employing phenolphthalein indicator. The factor for the H_2SO_4 V.S. was found to be 1.0391.

The Ammonium Sulphate method was carried out by accurately weighing 2 small beakers, adding 25 cc. of the H_2SO_4 V. S., an excess of redistilled ammonia water, evaporating to dryness on a water bath, then heating in an air oven at 110°C for periods of 20 minutes until the weight became constant, when the weight of ammonium sulphate was calculated to sulphuric acid. To avoid contamination with silica, at the time of making the test, strong ammonia was placed in a test tube and the gas distilled into distilled water.

The factor for the H_2SO_4 V.S. was found to be 1.0385.

The Sodium Carbonate Method was carried out by employing Merck's reagent anhydrous sodium carbonate, heating in a platinum dish a few minutes, quickly transferring to a stoppered weighing bottle and after cooling weighing off a portion for analysis, which was dissolved in water and titrated against the V.S. H_2SO_4 using methyl orange indicator.

The factor for the H_2SO_4 V.S. was found to be 1.0409.

The Oxalic Acid Method was carried out by weighing off portions of Merck's reagent oxalic acid crystals, dissolving in water and titrating against the potassium hydrate solution, using phenolphthalein indicator.

This potassium hydrate solution was then employed to standardize the acid

*Read before the New York Branch of the A. Ph. A., April 13, 1914.

using 25 cc. of the latter, titrating in hot solution, employing phenolphthalein indicator.

The factor of the H_2SO_4 V.S. was found to be 1.0398.

The Silver Chloride Method was carried out by taking 25 cc. of HCl V.S., about 200 cc. distilled water, adding an excess of one drop of silver nitrate solution, heating to boiling, allowing to stand until granular and filtering and washing on Gooch Crucibles, which after drying on the hot plate were weighed. From the weight of silver chloride the quantity of HCl in the solution was calculated.

This V.S. HCl was then run against the KOH solution, titrating in hot solution and this KOH run against the V.S. H_2SO_4 in hot solution, phenolphthalein being the indicator employed.

The factor for the H_2SO_4 V.S. was found to be 1.0367.

The Barium Sulphate Method was carried out by precipitating the H_2SO_4 in 25 cc. quantities of the V.S. H_2SO_4 , the barium chloride solution which was boiling being added from a pipette drop by drop, to the boiling H_2SO_4 solution which had been diluted with water.

The material was allowed to stand on the hot plate until the solution became clear and then filtered through Gooch Crucibles, which after being washed, dried and heated were weighed as barium sulphate from which the quantity of H_2SO_4 was calculated.

The factor for the H_2SO_4 V.S. was found to be 1.0440.

All the determinations were run in duplicate and yielded remarkably close checks.

The following table shows at a glance the results by the various methods:

Potassium Bitartrate Method (U. S. P. VIII)	Factor	1.0391
Ammonium Sulphate	"	1.0385
Sodium Carbonate	"	1.0409
Oxalic Acid	"	1.0398
Silver Chloride	"	1.0367
Barium Sulphate	"	1.0440
		<hr/>
		6 6.2390
		<hr/>
		1.0398

With the exception of the barium sulphate figure the results agree closely, but notwithstanding the fact that this is a trifle higher it has been included in making up the average to derive the factor.

Numerous determinations made on sulphuric acid solutions always yielded a higher result by this method than by others.

This sulphuric acid was originally standardized on June 4, 1912, and the factor which was the average of all the methods was 1.0388.

Considerable fungus growth being present in the solution the work detailed in this paper was begun and carried out on November 12, 1913, the factor which was the average of all the methods being as above noted 1.0398 the difference between the two figures after about 17 months being 1.0398—1.0388=.001, which proved that the age of the solution and the growth in it had not affected it.

As pointed out by Clark, (Proc. Amer. Pharm. Ass'n, 1910, page 978) a volu-

metric solution whose factor has not changed more than four points in the third decimal place in titrating 25 cc. of one solution against 25 cc. of another solution is regarded as not having changed its strength.

These results indicate that any of the above methods may be used with perfect safety for the standardization of volumetric acid and alkali solutions although our personal preference is for the ammonium sulphate, sodium carbonate, and potassium bitartrate methods.

I would take this opportunity to acknowledge my indebtedness to my assistant, Dr. I. Swartz, for his work in carrying out some of the duplicate determinations.

SOME FACTS AND DEMONSTRATIONS ON LLOYD'S REAGENT AND ALCRESTA ALKALOIDS.*

DR. GUSTAV REHFELD, ST. LOUIS.

I am very glad that you afforded me an opportunity to address you to-night and I hope to be able to interest you.

I feel that Lloyd's Reagent and the Alcresta Alkaloids will prove to be, in the near future, a matter of great importance in the fields of exact and applied sciences.

It has occurred many a time in the past, that apparently trifling circumstances were instrumental in revolutionizing the fields of human endeavor. Every one of you is familiar with the cause that gave the first impulse to the evolution of the laws of gravity, how the swinging of a candelabrum affected the science of physics, how an accidental arrangement of lenses fostered the invention of the telescope and the microscope, how the insignificant popping of the lid of a tea kettle brought about the wonderful development of steam power. It is unnecessary to enumerate any further; you know that most discoveries had their starting point in just such every day occurrences; millions and millions of times they happened and millions and millions of times they passed unrecognized until some one somewhere caught the revelation and thereby enriched human knowledge generally, opening up new view points and thus engraved his name indelibly on the pages of historical record.

I feel that the discovery of Dr. John Uri Lloyd is destined to do just such a thing, to change our viewpoints considerably, to make our knowledge more exact in a field that is not altogether easy of treatment and which will, thereby, benefit mankind generally, as it affects chemistry, medicine and pharmacy.

I wish to say to you though, that some time will elapse before the far reaching results, which we expect to get, will be realized. However, enough facts have been established to leave no doubt whatever, that this discovery will affect chemical research in alkaloids; that, already, it has given the medical profession a most valuable addition in *materia medica*, and to the pharmaceutical profession a means of rendering intensely bitter substances absolutely tasteless.

A few years ago Dr. John Uri Lloyd, of Cincinnati, discovered that a very

* Read before the St. Louis Branch, March 20, 1914.

common substance, aluminum silicate, in hydrated colloidal form, acted as an alkaloidal attractive. He investigated this phenomenon for a long time together with Dr. Waldbott, of Cincinnati, and about a year later Dr. Felter established the physiological action of its strychnine compound.

Some time after, Drs. Wiley, Wilbert and Kebler, all of Washington, D. C., were made acquainted with the alkaloidal energies of this substance, and toward the middle of 1913, Drs. Gordin and Fantus, of Chicago, contributed the first general papers on the subject. And this is about all that is known on this subject to date, as far as published reports are concerned.

Through the courtesy of Eli Lilly & Co., whom I have the honor to represent, I am enabled to-night to exhibit before you as a representative body of the St. Louis Branch of the A. Ph. A., the first samples of Lloyd's Reagent and a few Alcresta Alkaloids. These names were given to these products to individualize them, as standing in a class of their own. Your Branch is the first in the world to see and possess these preparations, as I have been permitted by Eli Lilly & Co. to present them at the end of my talk to the St. Louis College of Pharmacy.

Lloyd's Reagent, as stated before, is hydrous colloidal aluminum silicate. However, the various forms of natural aluminum silicate possess usually very slight alkaloidal affinities in their crude condition. In order to obtain uniform results, it became necessary to prepare it in a particular manner from a specially selected quality of natural hydrous aluminum silicate. Through the well directed efforts of our scientific department, we are enabled to-day, to supply Lloyd's Reagent of uniform attractive strength.

You will have noticed that I used the word attractive, where another word, reagent, would, apparently, have been more appropriate, but I did so, because our ideas of chemical reagents are pretty well established, and as Lloyd's Reagent acts electrically, it seemed the better word.

Lloyd's Reagent is practically insoluble in all liquids, and an excess is therefore inconsequential. Please bear this in mind when I shall demonstrate its energies before you to-night. When we add Lloyd's Reagent to a solution of alkaloidal salts, they are at once removed and held firmly in aluminum silicate combination. This holds true with the natural alkaloid compounds investigated to date; however, one exception should be noted and that is caffeine. It takes repeated treatment with Lloyd's Reagent to remove it from solutions, and this confirms our findings that caffeine is a feeble alkaloid. It certainly is feebly attracted by Lloyd's Reagent, and removed with difficulty, as I said before.

A very noteworthy feature of this Reagent is, that it has no affinity for other substances, especially those that are usually associated with alkaloids in plant-glucosides. It is, therefore, possible, as a matter of fact it has been successfully accomplished, to remove the alkaloids from fluidextracts without disturbing any of the other active or inert constituents as in the case of ergot. In order to facilitate the action of Lloyd's Reagent, the solutions should be acidulated.

As this reagent acts electrically, you will not be surprised to learn that the alkaloidal salts do not undergo any chemical change at all. In other words, quinine sulphate, morphine sulphate, strychnine sulphate, etc., will be removed as quinine sulphate, morphine, or strychnine sulphate as the case may be. But, note the remarkable phenomenon, that as long as these salts are in aluminum silicate

combination they are absolutely tasteless and not soluble in acid solutions any longer, while alkaline solutions destroy the electrical affinity gradually, and the alkaloids regain their bitter taste and previous solubility. This is of immense importance to internal medication. The Alcresta Alkaloids, being enteric, can be introduced into the system and directed to the very seat of the trouble without disturbing the functions of the stomach. Think what this means, for instance, in the case of ipecac; in fact with all, when employed in the treatment of intestinal disorders. The great usefulness of Alcresta Alkaloids becomes at once apparent, does it not? You readily will understand also, that these preparations are not intended nor destined to replace the old form of alkaloids, as both will have large fields of usefulness in therapeutics.

The affinities of Lloyd's Reagent for the different alkaloids vary greatly, as can be seen from the limited number of alkaloidal solutions investigated and listed; for instance, to precipitate:

- 1 Gram Cocaine hydrochlorate requires about 10 grams of Reagent.
- 1 Gram Cinchonine sulphate requires about 10 grams of Reagent.
- 1 Gram Cinchonidine sulphate requires about 10 grams of Reagent.
- 1 Gram Brucine sulphate requires about 7 grams of Reagent.
- 1 Gram Morphine sulphate requires about 4 grams of Reagent.

A correct list of all alkaloids investigated, will, no doubt, be given to investigators interested, by Eli Lilly & Co., upon request.

With your kind permission, I shall now demonstrate to you the efficacy of Lloyd's Reagent on various alkaloidal salt solutions. In order to remove any doubt, as to the presence of the alkaloids in these solutions, I shall first prove their presence by Mayer's Reagent, and after removing them by means of Lloyd's Reagent, shall demonstrate their absence by Mayer's Reagent.

I have chosen for this demonstration solutions of berberine sulphate, morphine sulphate, quinine sulphate and strychnine sulphate, all of the same strength, that is 1 percent.

Now as far as the recovery of alkaloids is concerned from their aluminum silicate combination, it is easily accomplished by means of ammoniated chloroform. In most instances the alkaloids can be removed from the dry powder, but where the alkaloid does not yield readily, the addition of a little distilled water is sufficient to bring about the desired result.

It probably will not be amiss to express the hope that later investigations of Lloyd's Reagent will bring about abbreviated and reliable methods of assay. Unfortunately, I am not in a position to-night to say whether or not we shall be able to do so. But let us hope that some one may be successful to evolve a short and reliable method by means of it. It would be an achievement of considerable moment.

I would like to call your attention also, to another matter which occurs to me should be investigated since we became acquainted with the mysterious activities of Lloyd's Reagent, and, that is, our filtering media. We are using talcum powder, pumice stone, kieselguhr, and others to help clarification of pharmaceutical preparations containing active ingredients. You know now what would happen if you were to filter an elixir containing alkaloids through Fuller's earth.

It seems to be that the electrical energies of the different media should be investigated, as unusually brilliant and otherwise elegantly appearing liquids may be devoid of active constituents, after filtration. As long as we do not possess positive knowledge about the electrical character of those substances, it may be wise to use paper pulp.

In conclusion, I wish to say to you, that Dr. Lloyd, as well as Eli Lilly & Co. stand ready at all times to render all possible service to further earnest scientific investigation. All inquiries for experimental supplies should be made to Eli Lilly & Co., Indianapolis, Ind., where they will find prompt attention.

INDISPENSABLE INSURANCE FOR PHARMACISTS.*

FRANKLIN M. APPLE, PHAR. D., PHILADELPHIA.

History has shown that it is the practice of shrewd, hard-headed, far-thinking men to protect their most valued possessions by some form of insurance. The greater the possibilities that they will suffer a severe loss from destructive forces, the more the desire to protect themselves from these agencies, and to increase the amount of the protection.

Our government has always recognized the wisdom of protection against all forms of invading and destructive forces by establishing agencies to conserve the desirable assets, as well as to repel the destructive invaders.

Our Army and Navy are supported and maintained chiefly to ensure peace to the nation by moral influence, and our Federal Public Health Service is depended upon to protect us from injury from organisms that would greatly distress, if not annihilate us if permitted to carry on their destructive work unimpeded.

Within recent years the wisdom of calling a halt upon the wasteful methods of handling our natural resources has been more apparent, and has given rise to an era of greater conservation, for we must admit that we, in large measure, are guardians of these wonderfully rich possessions for posterity, as they have been handed down to us by our forefathers. This conservation is but another name for insurance against waste and extinction.

Before me, as I pen these lines, lies the advertisement of a large bonding and insurance company, in which is described a form of insurance for almost everything that has a monetary value—even re-insurance of other forms of insurance; but to the pharmacist the most vital form of insurance is not included in the long list of classes of risks, viz., insurance of Professional Pharmacy, the backbone and sinew of the profession.

The omission of this form of insurance is excusable, for it is impossible for any company to write this kind of policy. It can only be obtained by co-operative action of pharmacists in a society, founded upon principles recognized to be honorable, unselfish, uplifting, ethical and of mutual benefit to its members and to society generally.

Such a praiseworthy assemblage of men and women is exemplified by the oldest

* Read before the Philadelphia Branch, March, 1914.

of pharmaceutical associations—The American Pharmaceutical Association, which was organized in 1852, in this city.

Why should a pharmacist neglect to protect his dearest possession—his professionalism, that for which he labored diligently and for which he was educated by special courses of instruction?

In these days of commercial greed and encroachment upon the domain of others' fields of endeavor, our calling has not been protected from the efforts of barons of wealth, to drag our profession down to the level of ordinary bartering and trading, to the great detriment of those specially educated to prepare and dispense medicaments for the sick and dying members of society; and to the ultimate, lasting disadvantage of the public, who oftentimes fails to appreciate the benefits it is enjoying until they are lost to it.

In the effort to find some means to protect us against the dangers which threaten our rights and liberties as a distinct professional calling, it is imperative that each pharmacist should seriously consider the necessity of affiliating himself with the American Pharmaceutical Association, which has an unsullied record of constant vigilance for the interests of pharmacy and its votaries for more than sixty years.

Just as the "Minute Men" of '76 gave instant heed to the call to duty in defense of their rights and liberties so to-day it is imperative for every true and loyal pharmacist to gather under the banner of the A. Ph. A., enroll himself upon its muster-roll and fight in defense of his profession and his existence.

The marvelous word "Drugs" has been seized upon by parties possessed of wealth to serve as a cloak for conducting mercantile establishments that are the worst cases of mis-branding known to me, and as such, should be punished as those who mislabel their goods are penalized by the provisions of the Food and Drugs Act. It is only by concerted, strenuous, untiring effort that we can hope to resist and repel these forces.

Do not be asleep and awaken too late to protect yourselves, but join with us to-day to repel those who would destroy the good name and fame of professional pharmacy.

I have intentionally avoided saying anything concerning the premiums charged by the Association for this insurance. Practically speaking, it makes no charge for the many benefits its members enjoy.

The mere pittance, five dollars per year, charged for membership, which includes The Journal of the American Pharmaceutical Association, is a ridiculously low charge for the post-graduate course of instruction in pharmacy that comes to one by mail in convenient installments monthly, to say nothing of the handsome cloth-bound volume known as "The Year Book," and in these days of enlightenment and advancement no one can worthily call himself a pharmacist who does not keep himself abreast of the times.

To describe the lines of activity of the Pharmaceutical Association is to cover every phase of pharmacy, as its many sections indicate the wide scope of its work.

It is impossible to speak of an effort to uplift, advance or to protect pharmacy without quoting from its archives; hence no one engaged in the drug business can honestly say that he has not and is not benefitted by the efforts of his co-

workers, who have banded themselves together to protect pharmacy, under the respected and revered banner of the American Pharmaceutical Association.

The moral effect of a large membership is well known to all thinking men; hence if the effort of the present members and workers should be reinforced by your co-operation, even greater results could be obtained; therefore why delay doing your part to increase the effectiveness and stability of the protection you enjoy as a member of a respected profession.

Come, join our ranks and help to protect pharmacy against those who would destroy it.

Let me call your attention to the words of Lowell: "No man is born into the world whose work is not born with him; there is always work and tools to work withal; for those who will and blessed are the horny hands of toil."

THEORIES UNDERLYING THE USE OF ANTITOXINS AND VACCINES.*

A. PARKER HITCHENS, M. D., GLENOLDEN, PA.

The action of antitoxins has so definitely passed beyond the stage of pure speculation that I think there will be little difficulty in expounding the theories underlying their use. With regard to vaccines, likewise, we have come to describe more clearly their mode of action without the use of a terminology recognized only by the initiated few.

Out of studies in immunology—the science dealing with the mechanism of contagious diseases—have developed methods by which the body may be assisted either to prevent disease-producing germs from gaining a foothold, or to eliminate them after they have become established.

The disease-producing bacteria are classified in various ways according to their functions. For our present purpose, the classification of most interest is that which considers the bacteria according to their manner of causing disease. Thus we find that one group of bacteria produces definite, soluble, and diffusible poisons and that all the symptoms of the disease are dependent on the action of these poisons upon the tissues for which they have an affinity. The second group of bacteria, on the contrary, do not produce soluble and diffusible toxins in appreciable quantity—their effect is brought about by a much more complicated process. We believe the production of disease by this class of bacteria is not a function in which they alone participate, but is the result of their interaction with the body cells.

Belonging to the first class of bacteria, the only organisms of interest to us are the *diphtheria* bacillus and the *tetanus* bacillus. These produce soluble and diffusible poisons—*toxins*; and spontaneous recovery from these diseases depends upon the generation by the tissues of a substance which will neutralize the toxins—*anti-toxins*. The requisite antitoxins can be easily produced in animals and

*Read before the Philadelphia Branch, April 7, 1914.

transferred to the bodies of patients by administering the blood serum of the treated animals.

For obvious reasons, horses are generally selected for the production of antitoxin. The germs in question are developed upon a fluid artificial culture medium, veal broth. After the bacteria are removed from the full-grown culture, the sterile filtrate, containing the specific toxins, is injected subcutaneously into the horses. The horses react by the production of antitoxin. Enormous quantities of toxin are administered, and consequently enormous quantities of antitoxin are generated and stored in the blood serum of the animal. The antitoxins on the market then, consist of this blood serum either native or chemically treated so that the pseudo-globulin constituent of horse serum which carries with it the antitoxin principle is removed and furnished, in solution, in as pure a state as possible.

The strength of the antitoxin is determined by titrating it against toxin, the guinea pig being used as indicator. In defining a unit at present, there is no more reason to say that it is the amount that will neutralize 200 fatal guinea pig doses of a theoretically pure toxin, than there is, in defining an inch, to say that it has a definite relation to the circumference of the earth. Twelve inches make 1 foot, 36 inches 1 yard; 1000 units of diphtheria antitoxin constitute the immunizing dose, 5000 units the average initial curative dose; 1500 units is the official immunizing dose of tetanus antitoxin.

The action of diphtheria antitoxin may be clearly illustrated by imagining the disease to be due to a mineral acid generated within the body and poured into the circulation in constantly increasing quantities. According to the urgency of the case, let us inject a corresponding quantity of a harmless alkali. The acid is neutralized, the disease is controlled, and the fate of the patient now depends only upon the amount of damage done to the tissues before the alkali was administered.

In tetanus the case is slightly different. Tetanus toxin has a strong affinity for the nerve tissues, and the compound formed by this union cannot be split up by antitoxin. After symptoms of the disease have developed, there is but one hope in treating tetanus with antitoxin. If the treatment has begun before the lethal quantity of toxin has been fixed by the nervous tissue, and if the amount of antitoxin then administered be sufficient to neutralize the free toxin in the blood, there is a chance that recovery may ensue.

Bacterial Vaccines. For a clear understanding of the action of bacterial vaccines, it may be helpful to consider this subject from the standpoint of our knowledge of anaphylaxis. Anaphylaxis, in its derivation, means a lack of resistance—it is the opposite of prophylaxis. Richet, in his investigation of certain poisons derived from sea urchins, noted that an injection of these poisons into a dog, instead of rendering the animal immune to a second dose, actually made him more susceptible. The work of Rosenau and Anderson showed still more clearly the operation of this phenomenon.

Anaphylaxis concerns the effect of proteins or albuminous substances upon animals; it concerns *all* proteins whether they are poisonous in themselves or not; for instance, egg white and normal horse serum act precisely as the proteins of the plague bacillus or of the typhoid bacillus. And furthermore, the proteins of

dead bacteria act practically in the same way as the proteins of living bacteria. It must be remembered, however, that anaphylactic symptoms can be produced only by proteins foreign to the animal; that is, anaphylaxis cannot occur in a guinea pig from the repeated injection of guinea pig serum, nor can the symptoms be produced in a horse by the injection of horse serum.

If we inject a normal guinea pig with a dose of protein parenterally—that is, by any route except by the gastro-intestinal canal—it does not appear to suffer the slightest inconvenience. If, however, we inject this animal two or more weeks later, with the same protein, it will die within one or two minutes and with very definite symptoms accompanying death. This is a manifestation of anaphylaxis.

For an explanation of this phenomenon we must go back to the work of Prof. Victor V. Vaughan upon the chemistry of the protein molecule. Vaughan has shown that a protein, treated chemically according to his method, is split into two parts—the one poisonous, the other non-poisonous. The *poisonous* part obtained from all proteins is the same whether it results from the splitting of egg white or from the splitting of typhoid bacilli, the symptoms leading to death in the guinea pig are identical. This poisonous part then is a poison and has no other function nor effect; one dose has no bearing upon the effect of a subsequent dose, no hyper-susceptibility is produced, and no tolerance, even by repeated administration.

The *non-poisonous* part, on the other hand, is specific in its action. The non-poisonous part of typhoid bacillus protein will immunize an animal against typhoid infection, but not against infection with colon bacilli; the non-poisonous part of horse serum will sensitize a guinea pig to horse serum, but not to goat or sheep serum.

These results of Vaughan's work upon the chemistry of proteins suggest an explanation of the mechanism of anaphylaxis; they show us that instead of being the opposite of immunity, anaphylaxis is merely one of its manifestations; and furthermore they give us a clearer understanding of immunity itself.

When foreign proteins are injected into the tissues of an animal, the body cells at once set to work to remove this protein. They prepare a ferment capable of splitting the protein molecule, which possibly because of its size is not diffusible, into smaller fractions able to pass into the circulatory system and be thence eliminated. These fractions of the protein molecule are similar to those obtained by Vaughan in his chemical splitting; that is, a *poisonous* part which, after the first injection, is liberated slowly and is therefore harmless in its effect, and a *non-poisonous* specific part which stimulates the body cells to produce a specific ferment-like substance. About two weeks after injection, the protein has been entirely removed from the tissues, the poisonous part has been eliminated so gradually that no symptoms have resulted, and the non-poisonous part has stimulated the tissues to generate a large amount of specific protein-splitting ferment.

At this point we must pause to note that according to Vaughan, the protein-splitting ferment includes the anti-bodies so difficult to understand in the theories of the German and French schools of immunity. This theory of the American school does not contradict the fact established by Metchnikoff, and further eluci-

dated by Wright, that the white blood corpuscles play an active part in the removal of foreign proteins whether they be cells or fluids; nor is it out of harmony with the theory of Ehrlich, who gives to the group of anti-bodies—collectively the “ferment” by Vaughan—different names according to their functions.

The guinea pig, then, at the end of two weeks after the first injection of, let us say, horse serum, contains in his tissues no trace of horse serum; but he does have within his body a large quantity of protein-splitting ferment, which may remain in the tissues for a long time; and even if it disappears, the power to generate this ferment upon demand may remain permanently. If we now inject into this guinea pig a second dose of horse serum the proteins contained therein are at once attacked by the specific ferment; digestion occurs almost immediately, resulting in the liberation of a large quantity of the poisonous part of the protein molecule; the animal is overwhelmed by it and dies, usually in less than five minutes. A dose sufficiently large to cause death depends upon the method of injection; if injected into the circulation or into the brain 1/20 cc. is sufficient; if injected subcutaneously, however, at least 5 cc. is usually necessary.

Now as to the bearing of this phenomenon upon infectious disease—Vaughan has used typhoid fever as a typical illustration. Infection results from the entrance of a few typhoid bacilli into the tissues under circumstances which permit their growth and multiplication. There is normally present in the body a small amount of a non-specific protein-splitting ferment which attacks the typhoid bacilli, liberating the non-poisonous part which in turn begins to stimulate the tissues to the production of a specific anti-typhoid ferment. We know that in guinea pigs it takes from 8 to 14 days to produce enough ferment to cause serious symptoms of intoxication upon the injection of a second dose of the protein. Now this period corresponds exactly to the incubation period in typhoid fever. It is during this time that the typhoid protein-splitting ferment is produced in increasing quantities while the typhoid bacilli are rapidly growing in numbers. The ferment sets free the poisonous part in gradually increasing quantities with the appearance and progressive increase of fever and the other symptoms of the disease. This process continues up to the point where the number of typhoid bacilli destroyed each day equals the number reproduced in the lesion. This balance is maintained for a time until the number of bacilli destroyed exceeds those reproduced.

A patient recovered from typhoid fever, has remaining in his tissues a large amount of typhoid protein-splitting ferment, so that when typhoid bacilli again gain entrance to his tissues, they are at once attacked and destroyed before they have a chance to develop. Obviously there is no intoxication because the amount of typhoid proteins is infinitesimal compared to the amount necessary to result in anaphylactic shock.

It is now easy to understand the action of typhoid vaccine. When we inject beneath the skin a number of typhoid bacilli, their disintegration is started by the normal proteolytic ferments in the body. A second and third dose given at intervals of about 10 days increases the quantity of specific typhoid protein-splitting ferment. The theory of typhoid immunity by means of bacterial vaccines applies equally to the production of immunity to other infecting bacteria. The theory underlying the use of bacterial vaccines in disease is based on the

fact that the tissues affected are unable to produce a sufficient quantity of the specific ferment to overcome the infection. The injection of bacterial proteins in a healthy part of the body leads to the production there of these anti-bodies which are conveyed to the focus of infection through the circulatory system and thus assist the local cells.

It will now be clear that the requisites to success in vaccine therapy are, (1) that the vaccine injected must contain bacterial proteins identical in kind with those causing the infection; (2) that the ferment produced locally must come in contact with the infecting bacteria. For one with proper training it is not hard to determine the kind of bacteria causing an infection; nor is it hard to obtain either a stock vaccine representing these bacteria or to prepare an autogenous vaccine identical with them; and it is a very simple matter to inject these bacterial suspensions beneath the skin of the patient.

If the patient is not in the last stages of disease, there is not one chance in many thousands that his tissues will fail to produce the proper anti-bodies or ferments. If the patient shows no improvement as result of the treatment, it behooves the physician to use means by which the ferments may be induced to perform their function.

In some infections, as in staphylococcic infection, accessory measures are seldom needed, while in streptococcic infections they are nearly always necessary. In gonococcic infections of the urethra and prostate, the mere injection of vaccines accomplishes but little; in gonococcic infections of the joints, however, the vaccine is apparently sufficient.

We are indebted to Besredka of the Pasteur Institute in Paris for an improvement upon bacterial vaccines which constitutes a real advance in vaccine therapy. As said above, when the bacterial vaccine is injected beneath the skin a small quantity of the protein is split up by natural ferments and the specific non-poisonous part thus liberated stimulates the production of ferments which continue the disintegration until the maximum effect of the vaccine is obtained.

The ferment itself is composed of at least two constituents; one is specific and by Ehrlich has been called *amboceptor*; (the *opsonin* of Wright is a similar anti-body). This substance has the power of fixing itself to the bacteria, thus preparing them for digestion by another substance which is not specific but is always present in the blood of healthy animals, and because the latter completes the ferment action, it is called *Complement*. Besredka proposed that amboceptor be utilized to prepare the bacteria for the immediate action of the complement. Bacteria thus prepared for the action of the complement were said to be "sensitized" and the suspensions of such bacteria were called by him "sensitized vaccines." The advantage they have over ordinary bacterial suspensions is that they eliminate the period during which the specific ferment is being formed. "Sensitized vaccines" have already been used extensively in France and also to a certain extent in England. The published reports amply attest their superiority.

Anti-bacterial Serums. The so-called "therapeutic or anti-bacterial serums" include anti-streptococcic, anti-pneumococcic, and anti-meningococcic serums. These are prepared by the injection of horses, first with dead, and then with living bacteria. In the case of anti-meningococcic serum, injections of autolysed bacteria are alternated with the cocci themselves. The autolysate contains a toxic

substance which causes the production of some antitoxin. This serum, like anti-dysenteric serum, partakes therefore of the nature of both an anti-toxic and an anti-bacterial serum.

These serums depend for their activity upon substances called ferments by Vaughan, but according to the nomenclature of Ehrlich, "Anti-bodies;" that is, substances antagonistic to the bacteria. Used in sufficiently large doses, anti-bacterial serums have undoubtedly great value. The chief difficulty lies in the fact that no method has so far been found by which anti-bacterial serums can be produced comparable in potency with diphtheria antitoxin.

It is well known that a much larger dose of any curative serum must be used if it is injected subcutaneously than if injected intravenously. Realizing this fact and the relative weakness of anti-bacterial serums, there is but little doubt that their use intravenously will be resorted to in the future with increasing frequency.

Summary. 1. There are two classes of bacteria with regard to their method of producing disease: (a) those that produce soluble and diffusible toxins, and (b) those that do not.

2. The toxin-producing bacteria are the diphtheria bacillus and the tetanus bacillus.

3. Antitoxins, produced by injecting horses with the specific toxins, are antagonistic to the specific toxic products of the bacilli in a manner very similar to the antagonism between acid and alkali.

4. To the second class belong the great majority of the disease-producing bacteria.

5. The symptoms in the diseases caused by the latter, are probably the result of the action of their specific metabolic products, combined with the effect of the liberated poisonous part of their protein molecule.

6. Recovery from such infectious diseases depends upon the production of sufficient specific protein-splitting ferment to remove their causative bacteria from the tissues.

7. The amount of this specific protein-splitting ferment may be increased by injecting bacteria of the same kind beneath the healthy skin.

8. Immunity from infectious disease depends upon the existence in the tissues of sufficient specific protein-splitting ferment to dissolve invading bacteria before they have a chance to develop.

9. The rational administration of bacterial vaccines presupposes accurate diagnosis and the administration of bacteria identical in kind with those causing the infection. It depends furthermore upon the ability of ferments and antibodies to come in contact with the infecting bacteria.

10. "Sensitized vaccines" are superior to ordinary vaccines because they reduce the preliminary period during which the injected bacteria are being split up so that the non-poisonous part may be available for the production of specific antibodies.

11. Anti-bacterial serums—anti-streptococcic and anti-pneumococcic—depend for their activity upon their content in specific anti-bodies or ferments.

12. The amount of these ferments in even the best serums is relatively small and the serums must therefore be used in larger doses than has been customary in the past.

13. Anti-meningococcic serum is both anti-bacterial and antitoxic.

14. Since the efficiency of curative serums is increased many fold when administered intravenously, this route will be used more frequently than has been the custom in the past.

A CONSIDERATION OF AUTOGENOUS VACCINES.*

B. B. VINCENT LYON, M. D., PHILADELPHIA, PA., PATHOLOGIST TO METHODIST EPISCOPAL HOSPITAL; ASST. PATHOLOGIST TO GERMAN HOSPITAL.

Empiricism is dying. Throughout the last century and particularly its latter decades, the searchlight of truth has lighted up many of the heretofore dark places in the study and practice of medicine. The discovery of the causation of many diseases through bacterial agencies was epoch-making and led the way naturally toward the introduction of measures able to cope with such a foe.

During the last thirty years scores of men have been at work on this problem and have each added their little to the sum total of our present knowledge and from the time of Jenner one startling etiologic and therapeutic discovery has followed another, so that among the names destined to live will always be found those of Pasteur, Koch, Pfeiffer, Ehrlich, Behring, Wassermann, Nogouchi and others.

Bacteria are divided into two classes, the good and the bad—Saprophytic and Pathogenic. The Saprophytic bacteria are scavengers; they thrive best on dead tissues and assist in freeing the body of many waste products. Pathogenic bacteria thrive best on the living tissues of the host in whom they are capable of producing disease. Their pathogenic action is due to the liberation of the toxins they contain or the elaboration of poisons in the tissues of the host.

Of these bacterial toxins there are two main types: The Exo-toxins, contained in bacteria whose poisonous principles are capable of being dissolved out of the bacterial cell. To this class belong the Bacillus of Diphtheria and the Bacillus of Tetanus. The great majority of bacteria, however, produce Endo-toxins, or poisons which are incapable of separation from the cell bodies by any of our known filtration methods. Examples of this are the Bacillus of Typhoid Fever and the Streptococcic and Staphylococcic groups.

While bacteria are capable of producing disease it is not through their mere presence *per se*, for as we know, our persons in health permit of the culturization of numerous pathogenic bacteria, therefore, other factors must enter in and these factors comprise the natural defensive mechanism of the body against disease.

Natural Resistance: This varies greatly with the individual and has a certain selective action, for why is it that one person can harbor in his mouth virulent Pneumococci and Streptococci and yet can go through life without a single attack

*Read before the Philadelphia Branch, April 7, 1914.

of pneumonia and, conversely, be subject to repeated attacks of tonsillitis, whereas, another individual harboring the same organisms may have several attacks of pneumonia during his life time and none of tonsillitis. This is due to the development of what we call *immunity*, which is the power of resistance the body tissues are capable to exert against bacterial poisons. *Immunity* may be divided into *species* and *racial immunity*.

Species Immunity: It is well known that many animals are naturally immune to disease common to man and that it is only with the greatest experimental difficulties that infections with these diseases can be made successful.

Racial Immunity: Also among the different races of the same species there appears to be a natural immunity against certain diseases, which have long been prevalent in that particular section, and which when carried to another section where fresh soil is obtained immediately light up into virulent epidemics. This is seen in the ravages of tuberculosis among the Negroes and the American Indians, and it is seen conversely in the immunity from yellow fever that has long been enjoyed by the Negro.

Acquired immunity is the protection that is afforded an individual who has passed through an attack of one disease, this conferring a greater resistance to that disease in the future. This is commonly observed in diseases like typhoid and yellow fever. Acquired immunity may be either active or passive. The process of conferring protection by treatment with either an attenuated form or a sublethal quantity of the infectious agent of a disease or its products, is spoken of as "Active Immunization," because the immunized individuals gain their power of resistance by taking an active physiological part in the acquisition of this new property of "Immunity." Thus active immunity can be acquired by repeated injections of attenuated cultures, as in Pasteur's work in hog cholera; by injections of sublethal doses of virulent bacteria as demonstrated in the protozoan disease of Texas fever; by injections of killed bacteria, first suggested by Chauveau. This method of active immunization with gradually increasing doses of killed bacteria, has been carried out successfully against many bacterial diseases. It is particularly useful against those groups of bacteria producing Endo-toxins and finally by injections with bacterial products from poisons excreted or liberated from the bacterial cell body. These measures comprise *vaccination*.

Passive immunity, on the contrary, is that gained by the host through no active formation of anti-bodies on its own part, but rather accepting ready to hand the anti-bodies prepared by the tissues of another species. The most conspicuous types of this are the anti-diphtheritic and anti-tetanic sera. These are both designed to meet bacterial exo-toxins and it is this type of sera that is most successful. On the contrary anti-gonococcic, anti-streptococcic sera and the like, which depend for their activity on the lysin, opsonin and other anti-bodies they contain, are not blessed with a like therapeutic success. Allen states that "these sera are not always curative, indeed, their use during active disease may not be altogether free from danger. Thus the administration of anti-cholera or anti-typhoid serum, which each depend for their activity on the lysin they contain, may result in the extra-leucocytic lysis of so many bacteria that the resultant

flooding of the tissues with large quantities of their contained endotoxin may imperil the life of the recipient from the additional toxæmia."

Bacteria have a selective action, not only must they gain access to the body in large enough numbers and possessing sufficient virulence, but they must also gain entrance to a tissue that is suitable for their further development. For instance, you can rub a typhoid culture into an abraded surface of the arm or a culture of streptococci can be swallowed, both with equal impunity, but reversing the conditions a bacterial infection is sure to follow.

Now what are the general defenses of the body against this bacterial invasion? They are fourfold:

1. *Antitoxins*, or substances manufactured by the tissues which are capable of neutralizing the soluble toxins produced by certain groups of bacteria.

2. *Agglutinin*, a substance which causes bacteria free in the tissues of blood stream to be clumped together in masses and held nearly immovable and therefore more accessible for phagocytosis. This is the more conspicuous where it concerns the motile bacteria. Though originally observed in 1889 by Charrin and Rogers, in studying the *Bac. Pyocyaneus*, the agglutination reaction is commonly associated with Widal, who first applied the phenomenon in the diagnosis of disease by an unknown organism.

3. *Lysin*, a substance or substances elaborated by the body which has the property of dissolving certain bacteria. Pfeiffer noted that guinea pigs which had been immunized against cholera bacilli could withstand the intra-peritoneal injection of further virulent cultures without harm and found that the peritoneal fluids dissolved the organisms.

4. *Opsonin*, discovered and named by Wright, is a substance that prepares or sensitizes the bacteria for ingestion by the phagocytic elements of the white blood corpuscles.

There are two types of bacterial infection, local and general. The former is best represented by boils, the latter is seen in diseases like typhoid fever, pneumonia, puerperal sepsis and the like. When a person recovers from a bacterial disease like typhoid fever, it is by the body having gradually elaborated the foregoing anti-toxins, agglutinins, lysins and opsonins in amount sufficient to cause the neutralization, destruction and solution of the bacteria. The time required in the manufacture of these substances varies in different diseases, 21 to 28 days, as a rule, in typhoid fever; 9 to 11 days, as a rule, in pneumonia, etc. So we have two biologic methods of treatment, serum and vaccine treatment, and the principle of the former is to supply these protective substances ready made (passive immunity), and in vaccination to stimulate the tissues to reproduce them more quickly, and, in as much as diseased tissues are more sluggish, in locally manufacturing them, to utilize or exploit healthy tissues for the advantage of the enfeebled ones. This then is the scientific basis for the action of vaccines. And now what are vaccines?

Vaccines are emulsions of the bodies of dead bacteria killed in various ways and suspended in suitable dosage in a solution of normal saline.

There are two types of vaccines—heterogenous and autogenous. Heterogenous vaccines are prepared from infections similar to the case which is to be

treated, but from infected material not derived from the patient himself. This type of vaccine may be and usually is polyvalent; that is, cultures are obtained from several infections of the same nature, and therefore represent, possibly, several "strains" of the same organism. These heterogenous vaccines are commonly called "stock vaccines," perhaps, because they are prepared in quantities and held in readiness to be used in a given case on demand.

Autogenous vaccines are prepared from cultures grown from infected material and obtained from the patient himself. In other words they represent, and are specifically, the organism from the effects of which the patient is suffering and toward which you are assisting the patient to establish an immunity. Knowing these differences, it is not difficult to understand that biologists, bacteriologists, serologists and clinicians of the thinking type, are agreed that the autogenous group of vaccines fulfill best the scientific therapeutic requirements. Let me quote from an article recently published by a man whose authority is unquestioned: "With the exception of certain organisms, such as tubercle bacillus and the gonococcus, there is little reason for employing stock vaccines instead of autogenous, and there is abundant ground for believing that the use of stock vaccines will not only lead to carelessness of diagnosis and misinterpretation of the probable nature of the infection, with consequent administration of the wrong species, but will sometimes be directly harmful. I am well aware that the argument has been advanced that laboratories are not sufficiently available to practitioners in all sections to make it possible for them to obtain autogenous vaccines, and would reply that, in a measure, this may sometimes be true, but the general demand for stock vaccines has been artificially stimulated by manufacturers, and the practical application of this method of treatment has out-distanced the scientific investigation of its merits. Instead of wholesome growth with the gradual provisions of local agencies where autogenous vaccines could be obtained, an unwholesome growth of this mode of treatment has been stimulated and those who seek to keep up with the latest pronouncement of advertised literature find themselves in a position of dependence upon stock vaccines in many cases. There can be no doubt that in some instances stock vaccines are satisfactory. Staphylococcus and typhoid and tuberculosis vaccines are instances, but the other forms, and especially streptococcus and pneumococcus and mixed vaccines, are of very doubtful efficacy.

"Here we come upon the field or variability in the organisms themselves and unless a growth has been prepared from the patient himself, the strain may be entirely different and inappropriate. It avails little to use mixed strains which require the reduction of dosage of the one possibly present and available strain below the point of usefulness, because of the simultaneous injection of several other strains in the mixture, which are of no use, or practically useless.

"As for stock mixture of heterogenous organisms designed for the treatment of cases in which no sort of accurate bacteriological diagnosis has been made, too vigorous condemnation cannot be phrased."

In my own personal experience I have met with many cases referred to me by other practitioners, cases on whom various stock vaccines had been tried for various lengths of time, in various dosages, with absolutely no improvement, and which have responded with surprising promptness to an autogenous vaccine

and have established an immunity that in many cases has lasted for years, and I, personally, have used in some cases stock vaccines of differing types, giving them a thorough trial, only to become discouraged at their non-success, and have discarded them for autogenous vaccines, with gratifying results.

On the other hand, I believe that stock vaccines of a single or of a polyvalent single organism type have their place, and a very important place, of usefulness in the (46-69) hour interval that is often necessary to prepare the autogenous vaccine, after the bacterial identification in the specific case has been established, and I, almost uniformly, use this period to give one and sometimes two injections of the appropriate stock culture. Appropriate stock vaccines may also be used with advantage in association with autogenous vaccines in suitable cases.

A word or two now to ensure success in getting the proper bacterial results in culture taking:—The first principle is to obtain your material free from contamination, and this requires the observance of special precautions according to the kind of material that is to be cultured.

Urines: Should always be obtained by sterile catheter, after the external meatus has been properly cleansed, and drawn off into a sterilized flask or bottle to which no preservative is to be added. It is better to catheterize the day specimen into one receptacle and the night specimen into another.

Feces: Should be obtained urine free, and specimens from first and last portion of the stool obtained and studied.

Sputum: Should be obtained with greatest care, because for practical purposes no mouth is germ free, and alveolar pyorrhœa, infected tonsils and the like are so common. Before retiring, the mouth should be carefully rinsed with sterile water and the teeth brushed with a sterilized tooth-brush, and a closed vessel containing sterile water, placed at the bedside. In the morning, the mouth should again be rinsed thoroughly with the sterile water, gargled, and with the brush re-sterilized, by dipping in boiling water, the teeth should be thoroughly brushed, and then a few mouthfuls of clean sterile water should be swallowed. After this, the sputum should be expelled by coughing and caught in serial, sterilized, wide-mouth bottles (with sterile corks). It is best that only one or two masses of sputum should be expelled into any one bottle, and the bottles labeled and sent at once to the bacteriologist for immediate examination.

The sputum should, after direct examination of stained specimens to determine morphologically the different types that may be present, be then "whipped" through several petri dishes containing sterile water, to further free the bacteria from surface contamination, and the final washed specimen planted upon the different culture-media that appears best suited for their recovery in pure culture, as judged from the findings on the first direct examination.

Cultures taken from boils or from infected sinuses, from acne pustules, from tonsillar follicles, and the like, should be made only after thorough appropriate cleansing and disinfection of surface relations, and then taken from a second or third portion of the material, discarding the first, by means of a platinum wire or a sterile capillary glass pipette inserted well within the cavity.

Cultures from eye, ear or nose should be taken with appropriate measures to ensure success.

Blood specimens should always be obtained from a vein, preferably that at the bend of the elbow, by means of an all-glass sterilized syringe of a capacity of not less than 5 cc. It is rarely, if ever, necessary to cut down on a vein, but the arm should be thoroughly sterilized by tincture of green soap and water, by 5-10 percent lysol, by absolute alcohol and finally by ether—personally, I prefer not to use iodine. It is better to moderately tourniquet the upper arm before sterilizing in order to prevent thin-walled veins from collapsing under the pressure. The blood should be immediately plated and flaked in peptone and dextrosed-broth.

In pulmonary abscesses, in suitable cases material may be obtained by lung puncture in the following way:—after sterilizing the chest wall in the same manner as for blood cultures, the needle attached to an all-glass syringe containing 3 cc. of peptone broth should be plunged into the lung at the proper point, as determined beforehand by clinical means, and 1 cc. of the broth introduced and reaspirated as far as possible and tubed. This measure will yield results in many cases properly selected clinically.

After getting suspected infected material, direct examination by means of variously-stained slide specimens should be made to determine morphologically and by staining reactions and relations, whether one or more types of organisms are present and if the latter how many and what types, and then, aided by this knowledge, proceed to utilize the various culture media that will best ensure recovery of each organism in pure culture. Here is where the thoroughly trained bacteriologist will succeed and in the shortest time. It is often exceedingly difficult to recover a shyly growing streptococcus or tubercle bacillus occurring in small numbers, let us say from a urine practically alive with the bacillus coli. This may be accomplished by inhibiting or attenuating the growth of the hardier, more freely growing organism, by treating the culture medium in an appropriate manner, but unless this is accomplished it will be seen at once how useless it is to successfully treat pyelitis of streptococcal or tubercular origin by using only the B. Coli in the vaccine preparation. Hence the failure of many autogenous vaccines that are bacteriologically imperfect or incomplete.

In many cases of chronic gleet, however, the gonococcus is absent, and the catarrhal inflammation is kept alive by secondary invaders which may then, in combination, serve for cure in absence of the primary invader.

After getting out every bacterial group contained in a given specimen, each in pure culture, these should then be studied with a view to ascertain their share in the production or continuation of the disease in question and guided by experience, clinical as well as bacteriological, a final judgment of the organisms concerned may be passed and the proper ones selected for use in the vaccine. They may all be combined in a single ampoule or may be placed singly or in pairs. Only the lower dosages, however, can be reached by making a mixed vaccine composed of many elements on account of the combined dosage being too high to permit of safe injection.

We can now proceed to prepare the vaccine, in which the following steps are concerned:

1. To obtain an emulsion containing the bacteria impurity—an emulsion with a uniform suspension and as free from bacterial clumping as possible.

2. To standardize the emulsion—that is to determine how many bacteria are contained in each cubic centimeter.

3. To kill the bacteria in the emulsion and tube them—or

4. To decide upon the dosage of each ampoule or set of ampoules; to tube them still alive and then kill them.

5. To label, effectively, each ampoule and place them in sets of ten in compartment-boxes or cartons, the lids of which are to be specifically marked with the names of the organisms they contain and in what dosage and, most particularly, with directions for their use.

6. To be sure that all “controls” are sterile before allowing the vaccine set to leave the laboratory for use.

I shall not, in this paper, enter in detail into the technique required in the actual preparation of the vaccine, but I want to say a word or two of caution regarding the best ways of killing the bacteria without impairing their immunizing properties. This can only be accomplished by a thorough knowledge of an observance of the thermal death-point of each group of organisms; a knowledge that will tell you which bacteria should be killed by heat, and which by chemical measures, or by a combination of the two. If by heat, at what temperature and for how long sustained? If by chemical sterilization, by what chemical and in what strength? I have known many autogenous vaccines—otherwise quite appropriately selected bacteriologically and faultlessly prepared, to be inert and to fail absolutely therapeutically, for no other reason than that the thermal and chemical death-points were not carefully ascertained. And I doubt not that this applies equally to many stock vaccines.

Have we in vaccine therapy a means sufficient to combat all types of bacterial infections? I would answer emphatically “No,” and I would add that harm may often come from their indiscriminate use and from use in the hands of the inexperienced and careless.

In epidemic meningitis, in typhoid fever, in pneumonia, in generalized bacteraemia, with or without ulcerative endocardial lesions, the use of vaccines for curative purposes has not been attended with great success, although, occasionally, a case is seen in which amelioration in severity of symptoms has taken place which rightfully or wrongly has been ascribed to the use of the vaccine. I am by no means yet convinced that their use in such cases is unjustifiable and believe that we may yet arrive by experience at some method of establishing appropriate dosage and proper intervals of injection for this class of acute fulminating infections that will produce better results.

The most suitable field for vaccines, and the field in which the most brilliant results have been obtained, lies in treatment of diseases, acute or chronic, that have local foci of infection, such as, furunculosis, carbuncles, abscesses, various bone diseases, such as osteomyelitis, various skin diseases, such as acne-vulgaris, infected sinuses, pyelitis, empyema, various infections of the mouth, such as pyorrhœa alveolaris, infections of the nose and nasal passages, various post-gonorrhœal conditions and various diseases of the respiratory tract, such as pulmonary abscesses.

And now a final word as to why vaccines fail in the hands of many workers, even in the above field of election—it is chiefly because of insufficient knowledge

governing the general laws of dosage and time intervals of injection; by selecting inappropriate points of injection; by disregarding the best time of day at which injection should be given, so that the patient is not protected during the "negative phase" period, at which his anti-body formation is at the lowest ebb, etc., etc. For information upon many of these points I would refer the student or interested worker, to a close perusal of monographs on this subject, notably, Allen on "Vaccine Therapy."

Finally, I would call attention to a common cause of failure from a neglect to realize that autogenous vaccines need to be freshly renewed—i. e., a new culture taken and a new vaccine prepared from cultures that represent more nearly the *status praesens* of the case, for it frequently happens that, in long chronic conditions, the bacteria by mutation or other biological properties, become adapted more or less to the anti-bodies formed in the tissues of the host.

I was asked, before reading this paper to this body, whether I did not think it quite feasible and proper for druggists to establish autogenous and stock vaccine departments for the purpose of themselves *making* these products. I do not think it is practical, nor fitting that you should, nor do I believe that the attempt would prove, commercially, a success. And I will close with the words of Sir Almroth Wright, one of the pioneers in this work, who states that for such skilled service as that demanded for vaccine therapy,—“is required a man who has spent years of study to master the technic; to know how to make the vaccines; to know where to look for the microbes; to know how to isolate them; and, most of all, a man with sufficient experience and ability to apply all these things.”

DISCUSSION BY DR. JOSEPH HEAD.

Vaccine treatment is only successful when all the depots of infection of the body have been first eliminated by careful diagnosis and judicious treatment. This is particularly the case with pyorrhea alveolaris which I have treated with autogenous vaccines in over seventy cases. Judicious co-operation with the family doctor should be established. All local depots of infection in the mouth should be removed by surgical means in order that the antibodies formed in the blood by the vaccine should have full opportunity to come in contact with the areas of infected tissue. If this is not done and the bacterial masses are left around the teeth and in the gums the antibodies can only attack the exterior portions of this bacterial mass and failures will inevitably result from the vaccine treatment.

I have found in my bacterial examinations of pyorrhea-pockets that there are six principal germs, viz., staphylococcus, streptococcus pyogenes, streptococcus viridans, micrococcus catarrhalis, bacillus influenza, pneumococcus and diphtheroids. In the cases just mentioned these predominate in over 95%, there being an occasional scattering of tetragenus, Friedlander's bacillus and an occasional unrecognizable germ. The reason that my results have been so consistent is probably due to the fact that the technique used for obtaining the material for the autogenous vaccine is such as to exclude the extraneous flora of the mouth.

This technique is as follows: A thin platinum spear of 1/3000 of an inch in thickness is used for obtaining the material for the vaccine. The external portion of the pocket is cauterized with a cautery, then the thin platinum spear heated to a cherry red is plunged to the bottom of the pocket. When this is withdrawn the material contained thereon is supposed to come from the deep walls of the pocket where the controlling infection is supposed to reside. The spear, on being removed, is streaked across the blood agar and sent to the laboratory the same day, where the bacteria are carefully segregated and mixed, according to their species, in the sterile salt solution. Streptococci, micrococci catarrhalis, pneumococci

and bacilli influenza are made up 50 million to the cc. and staphylococci made up 300 million to the cc.

The dosage is a very important factor in this treatment. We should remember in giving vaccines that we are dealing with a substance as vital for good or evil as strychnine or belladonna. Vaccines are not simple remedies as Vaughan's investigations have so beautifully shown. It is my habit to start with a dose containing about five million streptococci and thirty million staphylococci. This is increased steadily week by week until either the full cubic centimeter is given or the patient shows signs of reaction which is made evident by nausea, congestion of the forehead, faintness, purging of the bowels or sharp neuralgic or gouty pains. When these are developed and last for over twenty-four hours, it is always a sign that the dose should be stopped temporarily for a week and then given in very much reduced quantities,—one-half at least. This should be slowly and cautiously raised again, and if possible, kept within the amount that will reproduce the reaction, as it has been my experience that small doses give better results than large. We should always be on the lookout for reaction in giving our doses. Sometimes five or six doses of the same size can be readily accepted and the seventh dose will give a sharp severe reaction. This, according to Vaughan, would indicate that the digestion of the vaccine in the blood has not been complete, and the protein poison is being developed faster than the body can eliminate it.

In closing, I would say that the vaccine treatment is of unquestioned value and in obstinate cases should always be given a fair trial.

A WORD ABOUT PACKAGES AND LABELS.

People are very exacting as to what comes from a drug store; not only must the goods be of the best quality, but the packages in which they are put up must appeal to the sense of neatness. The dry-goods clerk, the shoe clerk, the grocer—in fact, salesmen in all other trades—do not care much about the appearance of the packages they send out. A sheet of paper twisted or rolled around the article, a piece of string, and the thing is done; and nothing better is expected. But with the druggist it is different. We wonder how many druggists appreciate the effect of a neatly-tied package or a simple, neatly-printed label, upon their customers. And yet we know of people who prefer a certain store to another for no other reason than that the goods sent out of it are neater than those coming from the other. What is true of parcel wrappings also holds for labels. A great deal of improvement is noticeable in this respect within the last twenty years. We remember the fantastic labels sported in many drug stores at the time the Japanese art craze swept this nation. Label makers swam with the stream, and some of their efforts were gorgeous beyond belief—so gorgeous that the lettering on the labels was completely lost in the maze of decorative detail. Labels of this kind are seldom seen nowadays, but they turn up once in a while in some obscure village. The intelligent public would not tolerate such things nowadays.

Have your packages neat and your labels plain.—*National Druggist*.

INFECTION AND IMMUNITY—A REVIEW.

N. S. FERRY, PH. B., M. D., RESEARCH LABORATORY, PARKE, DAVIS & CO.,
DETROIT, MICH.

(Continued from page 568.)

6. SPECIAL PHENOMENA OF IMMUNITY. It has been shown that antitoxins, according to Ehrlich's scheme, are cast-off receptors of the first order, and that in order to explain other phenomena occurring in immunity, as agglutination, precipitation, cytolysis, bacteriolysis, and hemolysis, it becomes necessary to demonstrate other orders of receptors.

Agglutinins. In 1895 Grüber and Durham discovered that when a few drops of an antibacterial serum were added to a suspension of homologous or corresponding bacteria, the micro-organisms within a short time would be found in clumps. This phenomenon was termed agglutination, and was said to be due to definite bodies in the serum called agglutinins. The practical application of this reaction to the diagnosis of typhoid fever was brought out independently by Grünbaum and Widal, although Widal was the first to publish his results. The Widal reaction, or the phenomenon of agglutination, may be produced by most of the antibacterial serums, and observed, therefore, in many of the bacterial infections, although the reaction is variable, and is more specific and definite in some than others. The cast-off receptors or agglutinins, which have to do with the formation of the clumps in the phenomenon of agglutination, have not only a haptophore affinity as in the case of receptors of the first order, but also another group, called a zymophore group. When an animal is immunized to a certain micro-organism, these receptors of the second order are formed along with others, and many of them of course are liberated. These cast-off receptors or agglutinins, therefore, attach themselves to the specific bacteria by means of the haptophore affinity, and produce the agglutination by means of the zymophore group acting upon these attached micro-organisms. The haptophore group selects and picks up the bacteria, while the zymophore group produces the reaction.

Precipitins. The receptors concerned in the precipitation reaction are formed similar to those in the agglutination reaction. When the blood or serum of a human being is repeatedly injected into the peritoneal cavity of a rabbit, the serum of that rabbit acquires the property of precipitating the human serum, if mixed in the test tube. The receptors or precipitins are formed and liberated

during the injections of serum into the rabbit. These receptors have a haptophore affinity which attaches itself to the serum of the human being, while the zymophore group produces the precipitation. If the serum of this rabbit is mixed with the serum of any other animal, the reaction will not take place, for this haptophore group can only attach itself to human serum, and the zymophore group can only react when the haptophore group is thus attached. The reaction is, therefore, a specific test for the presence of blood.

Cytolysins. It has been found that when suspensions of various cells are injected into an animal, certain substances are formed in that animal and found in the serum which are injurious to cells similar to those injected. The cells injected may be bacterial cells, blood cells, epithelial cells, renal cells, hepatic cells, and others, but it must be borne in mind that the destructive bodies are specific only for the kind of cells injected. For instance, if we inject red blood cells from a human being into a rabbit, then the serum of that rabbit will be injurious to human red blood cells but not to kidney cells or liver cells, and not red blood cells of any other species. It can be seen that in order to explain this phenomenon it becomes necessary to have a more elaborate receptor or side chain than for any of the previous combinations. At least two distinct substances are formed which react upon the cells in question, and these two substances must be able to combine with each other before the reaction can take place. These two combining substances are termed amboceptor and complement. The amboceptor, the immune body or receptor, is formed by the body cells during the process of injecting the red blood cells, bacteria or other cells, while the complement is always present, and, therefore, a normal constituent of the serum. The immune body or amboceptor, which is the cast-off receptor, must not only be able to unite with the specific cell, similar to the antitoxin of the first order, and the agglutinin of the second order, but go a step further and unite with another substance or body, the complement. It therefore must have two haptophore affinities, one for the complement and one for the specific cell. The final reaction, the destruction of the cells, is produced, however, by the complement, and although this is present in the normal serum, it cannot perform its function without the aid of the amboceptor, which is only formed by the injection of the cells.

Opsonins. In studying the action of phagocytes on bacteria, it has been found that it is not primarily a reaction between the leucocytes and bacteria, as was thought by Metchnikoff and his school, but is a more complicated reaction. Wright and Douglas have demonstrated that certain substances in the blood serum are necessary before the reaction can take place. These substances which act upon the bacteria and prepare them for the leucocytes, are called opsonins. What sort of changes the opsonins produce in the bacteria, rendering them susceptible to the action of the leucocytes, is not known.

Hektoen and Rurdiger have shown that the opsonins resemble the toxins, in that they apparently have a toxophore and haptophore group, one to unite with the bacteria and the other with the leucocytes. The relationship between the opsonins and the other immune substances, as the agglutinins and cytolysins,

has practically been proven, so it appears that the opsonic theory represents a connecting link between the phagocytic theory of Metchnikoff and the side-chain theory of Ehrlich. It may possibly be demonstrated, in the future, that Ehrlich's theory is simply an aid in explaining the action of the phagocytes in infection, and that, after all, the leucocytes may have the most important part to play in the phenomena of immunity.

7. ANAPHYLAXIS AND SERUM SICKNESS. One of the best descriptions of anaphylaxis is given by Hiss and Zinsser. "By anaphylaxis is meant the following train of phenomena: When a foreign proteid is introduced by subcutaneous, intraperitoneal, intravenous or subdural injection (or in some cases by feeding) into the animal body, after a time there will appear a specific hypersusceptibility of the animal for this proteid. After a definite interval, a second injection of the same substance, harmless in itself, will produce violent symptoms of illness and often rapid death in an animal so prepared. The phenomena are not limited to any given class of proteids, but are manifest in the case of animal, vegetable and bacterial proteids, and within certain limits are specific." A typical reaction may be seen in a guinea pig which has been injected with normal horse serum. Following an extremely small initial dose of the proteid (0.004 cc.) the anaphylactic state usually develops after ten to fourteen days. After a large dose the time required for the development of the anaphylaxis is usually longer; it may even extend over weeks or months. Many theories have been offered for the explanation of the phenomenon of anaphylaxis, but none are at all satisfactory. Without going into the exposition of these different theories, we will take up one which seems to offer the most plausible and at the same time the simplest interpretation of all.

It has been found that the proteid molecule, on being split up by chemical methods, contains a toxic and a non-toxic substance. It has also been determined that this toxic substance is unlike the toxin formed by the diphtheria bacillus, in that it does not produce a neutralizing body similar to antitoxin, when injected into an animal. It does seem to produce, however, a substance or body resembling the hemolysins, termed proteolysin, which is capable of breaking up any molecule of the same substance, which may be subsequently injected after a certain length of time. The hemolysins break up the red blood cells, setting free the toxic portion. The toxic portion of the proteid molecule is extremely poisonous, and if enough is set free in the animal, fatal results will follow within a few minutes. By making a direct application of this theory, let us see how anaphylaxis may take place in a guinea pig. A small amount of horse serum (0.004 cc.) is injected into a guinea pig. The proteid of this serum contains a toxic substance, which, acting upon the guinea pig, produces a body we have called proteolysin. The body does not form at once, but appears to take about ten days, and when once formed will remain in the guinea pig for the remainder of its life. Now after the required interval the guinea pig is again injected with horse serum, this time, however, with a much larger dose. The body or substance, the proteolysin, which was formed by the guinea pig following the first dose of serum, now acts upon the proteid of the second dose of

serum, splitting it up at once into the toxic and non-toxic parts. On account of the large amount of serum constituting the second dose the amount of toxin set free must be relatively large, and acting upon the tissues of the guinea pig produce a train of symptoms recognized as the phenomenon of anaphylaxis. Vaughan and Wheeler, of Ann Arbor, were able to separate the proteid molecule into a toxic and non-toxic portion, and with the toxic portion experimentally produce symptoms similar to anaphylaxis, so it would seem that the theory so far is well founded.

The facts as regards anaphylaxis of which we are practically certain are as follows:

1. A condition of hypersusceptibility or hypersensitiveness is produced when a small quantity of proteid is injected, and a condition of immunity is produced when a sufficiently large dose is given.
2. The symptoms are more severe and specific the smaller the first or sensitizing dose, to a certain limit.
3. If a dose is given the animal some time between the first or sensitizing dose, after the first day, and the second or fatal dose, a condition of antianaphylaxis is produced which immunizes the animal to the fatal dose.
4. The condition of anaphylaxis may be transmitted from a sensitized animal to another through the serum, which is termed passive anaphylaxis.
5. The condition of anaphylaxis may be transmitted from mother to offspring.
6. Animals sensitized to one proteid are not sensitive to subsequent injections of other proteids; the reaction, therefore, being more or less specific.
7. The quantity for the second injection should be considerably larger than the first or sensitizing dose.
8. Animals recovering from the second injection are thereafter immune to the same substance.
9. After ten days following the sensitizing dose the animal is always susceptible to the second dose.

Other phenomena somewhat of this nature, which probably depend upon the principles involved in anaphylaxis, or at least in hypersensitization (allergy), are seen in the tuberculin and mallein reactions. The animal or individual is probably sensitized by the primary infection, while the injection of the mallein or tuberculin produced the typical reaction, which is slight, and which is due to the small amount of the dose. If the dose is large very severe symptoms or even death have been known to follow. Another condition or reaction, which has been compared to anaphylaxis, is that of serum-sickness. It has been known for several years that the injection of antitoxic sera in human beings is often followed by various skin eruptions, pain in the joints, swelling of the lymph glands, often albuminuria and fever. These symptoms appeared after an incubation of from two to ten days. It was also early found that these symptoms had nothing to do with the antitoxic reaction of the serum, but were dependent upon properties peculiar to the serum itself. Normal horse serum will produce

the same symptoms. It seems certain that anaphylaxis has something to do with these conditions, but we are unable to determine the exact relationship. Anaphylaxis in animals only follows the second injection, whereas serum-sickness often follows the first injection. The patient is the more liable to the condition the greater the number of injections given. The size of the dose does not seem to make much difference in serum-sickness. The phenomenon of serum-sickness is seen in about 20 per cent. of the cases injected with antitoxic serum. The symptoms may at times be troublesome, but fatal cases traceable to serum-sickness are unknown, or at least have not been proven. There are a few cases on record where death followed suddenly on the injection of antitoxic serum, but these are very rare, although very magnified by opponents of serum-therapy. This condition has been termed sudden death. While it would appear, in explanation of this condition, that the fatal symptoms were traceable in some way to anaphylaxis, other suggestions have been offered which seem much more plausible, as they have been to a certain extent, backed up by the post-mortem findings, such as the shock of the injection upon an already overburdened heart, or upon one suffering from the condition known as status lymphaticus.

Knowing that the larger part of the antitoxin is contained in the globulins of the serum, it has been found advantageous to use these globulins in the prophylaxis and treatment of diphtheria in place of the whole serum. As a result, the percentage of cases of serum sickness have been greatly reduced. This is explained on the assumption that as the amount of proteids injected are necessarily decreased, the chances of proteid poisoning are lessened. Although serum sickness is of less frequent occurrence than formerly, showing the relative increase in the safety of the globulin over the whole serum, yet a point has been raised as to the relative immunizing value of the globulins as compared to the whole serum, and, along the same line, the relative value of serums of high antitoxic potency as compared to those of low. It has been suggested that we do not obtain the same results, unit for unit, with serums of concentrated antitoxic content as we did when this method of specific therapeutics was first inaugurated and large quantities had to be injected due to the low antitoxic content of the serums. That is to say, some maintain that we do not obtain relatively the same therapeutic results, from the immunity point of view, with 1 cc. of a globulin containing 3000 units per cc. or 3 cc. of a serum containing 1000 units per cc. as we did with 10 cc. of a serum containing only 300 units per cc. This is a point which only time and experience can answer.

The following table will compare fairly well the three conditions, according to the facts we have been able to obtain up to the present time:

Anaphylaxis.	Serum Sickness.	Sudden Death.
1. Condition is manifest only after second injection.	1. Condition often manifest after first injection.	1. Condition usually manifest after first injection.
2. Symptoms appear within an hour. Difficult to kill within five minutes.	2. Symptoms usually appear after an incubation from two to ten days.	2. Symptoms appear immediately.
3. Very severe symptoms, usually resulting fatally.	3. Symptoms disappear within a few days and leave no bad results.	3. Symptoms always result fatally.
4. Fatal dose must be very large in proportion to therapeutic dose for man. 5 cc. for a guinea-pig, corresponding to 3 mints for a man.	4. Size of dose of little importance.	4. Size of dose apparently not important.
5. Animal must be "sensitized" by a previous dose of the same proteid, with an interval of at least 10 days.	5. Previous dose apparently not necessary.	5. Previous dose apparently not necessary.
6. If a dose is given the animal some time between the first dose and the fatal or second dose, the animal will be immunized to the last dose.	6. Not known; experimental.	6. Not known.
7. The condition of anaphylaxis may be transmitted from a sensitized animal to another through the serum (Passive Anaphylaxis).	7. Not known.	7. Not known.
8. The condition of anaphylaxis may be transmitted from mother to offspring.	8. Not known; may be possible.	8. Not known.
9. Animals sensitized to one proteid are not sensitive to subsequent injections of other proteids.	9. Not known; probable.	9. Not known.
10. Animals recovering from the second injection are thereafter immune to the same substance.	10. The patient is the more liable to the condition the greater the number of injections given.	10.

8. RELATION OF BIOLOGIC PRODUCTS TO IMMUNITY.

Bacterial Vaccines (dead bacteria), active immunity.

Smallpox Vaccine (attenuated virus), active immunity.

Blackleg Vaccine (attenuated organisms), active immunity.

Anthrax Vaccine, Pasteur (attenuated organisms), active immunity.

Antitoxic Sera (blood serum), passive immunity.

Antibacterial Sera (blood serum), passive immunity.

Tuberculin (dead bacteria and bacterial products), active immunity.

Rabies Vaccine (attenuated virus), active immunity.

PREVENTION OF GASTRIC DISTURBANCE BY SODIUM CARBONATE, IODIDS, OIL OF SANDALWOOD AND SIMILAR DRUGS.

EDGAR G. BALLENGER, M D., AND OMAR F. ELDER, M. D.

For a number of years we have been working to discover some method of obviating the gastric disturbance which is produced by remedies such as potassium iodid, oil of sandalwood, sodium salicylate, sodium carbonate, etc. This we have finally and satisfactorily accomplished. Remedies, such as oil of sandalwood, creosote and oleoresins administered in soft gelatin capsules may be prevented from disturbing the stomach by the process of hardening with formaldehyde the capsules in which they are placed.

Only slight hardening is necessary, especially if the capsules are kept for some time, as additional hardening comes with age. At first we immersed the filled capsules for one minute in a dilution of 1 part 40 percent formaldehyde solution to from 40 to 60 parts of water. The strength should vary with the aging allowed.

From the time that the dilution mentioned is used two weeks should be allowed to intervene before administering the capsules. A more satisfactory method of preparing the capsules is to place them in open boxes in a closed vessel in which they are subjected to the vapor of the solution of liquor formaldehydi. About 15 cc. of the solution should be used for each cubic foot of space in the closed vessel. The solution should be placed on cotton or gauze in a saucer or tray. The time required for hardening the capsules varies with the temperature and with the time that is to be allowed before they are administered. Six hours' exposure or less is enough for capsules which are not to be administered at once, while twelve hours may be necessary in preparing capsules for immediate use. These estimates are made for ordinary soft gelatin capsules at the ordinary room temperature, from 70 to 75° F. The capsules become hardened so that they are not digested by the gastric juice, but are digested by the intestinal secretion, if they have not been subjected too much to the vapor, in which case they may pass undigested. If dilatation of the stomach is present and the capsules or food do not pass into the intestines within the usual time, a greater degree of hardening of the capsules may be necessary. For the ordinary normal person capsules prepared as previously described will prevent gastric disturbances by carrying the medicament into the intestines before the capsules burst.

An even more satisfactory method of carrying through the stomach such remedies as sodium carbonate, potassium iodid, sodium salicylate, etc., is obtained by combining the desired remedy with mutton-suet and paraffin. When incorporated in such a mass the medicament is uniformly carried into the intestines without dissolving, as the stomach does not secrete a fat digestant. The suet is digested as it passes down the intestines and thus

gradually the drug embodied in it is liberated. The paraffin is added to give additional hardness. The following combination is recommended:

	gm. or cc.	
℞ Sodii carbonatis monohydrati.....	90	℥ iii
Potassii iodidi.....	90	℥ iii
Sodii salicylatis.....	90	℥ iii
Sevi	30	℥ i
Paraffini	16	℥ iv
M. et fiat mass.		

All the ingredients should be melted over water and while melted encapsulated in 00 gelatin capsules. The capsules may be filled with a fruit spoon. The melted mixture should be of a creamy consistency, and the salt used should be previously powdered. The encapsulated product is a mass of the salt, the suet and the paraffin, is hard and remains unaffected by the gastric juice.

In the use of sodium carbonate, in the treatment of Bright's disease, as suggested by Martin H. Fischer, we have found this method of administration of decided value, as formerly it was quite difficult for the patient to take alkali in sufficient amounts to render the urine neutral or alkaline without producing gastric disturbance, with coated tongue and other symptoms.

The manner in which albuminuria and casts have disappeared under this treatment has been quite remarkable. A number of patients who had been declined as risks by insurance companies because of albuminuria and casts have been passed by the insurance examiners after a few months of alkaline treatment. In order to secure the desired result we have added $\frac{1}{4}$ grain of phenolsulphonephthalein to each capsule of the monohydrated sodium carbonate preparation and have advised the patients to take from five to eight capsules daily as indicated to keep the urine light pink. This method constantly assists in regulating the amount of alkali to individual and varying requirements. The patients do not object to the use of the monohydrated sodium carbonate when so administered and can continue it over a prolonged period, when necessary. Potassium iodid so administered does not disturb the stomach, but produces its other physiologic and therapeutic effects.

In the use of remedies such as pancreatin, which it is desirable to liberate at once in the intestines and not to have dissolve slowly, ordinary gelatin capsules should be subjected to the formaldehyde vapor as suggested for the soft gelatin capsules. These capsules do not digest in the stomach and therefore carry the remedy they contain through without its being acted on by the gastric secretion. The remedies which we suggest to be incorporated in the suet and paraffin cannot well be given in ordinary gelatin capsules, as they may cause intestinal disturbance by liberating the entire amount of monohydrated sodium carbonate or potassium iodid at one point in the intestine instead of gradually freeing the mass as they pass down the tract.

We advise that in preparing the capsules controls of methylene blue and oil of sandalwood be used in test capsules. If the capsules have been insufficiently hardened a glass of carbonated water taken two hours after the

capsule has been administered will show by the eructation whether or not the capsule has broken in the stomach. If the capsules are subjected to formaldehyde vapor too long or if the gas be too strong the urine may be slow in becoming blue, or may remain unchanged. Capsules intended for immediate use may be subjected to considerably more formaldehyde than may be used on those which are to be kept for a few months.—*Journal A. M. A.*, Vol. 62, p. 197.

THE ART OF ADVERTISEMENT WRITING.*

A. W. BROMLEY.

Advertising is a branch of the art of business, but advertisement writing is a branch of the art of literature. If we could question the men who are writing the best of the advertisements we see in the daily press I am sure we should find that the majority of them have passed to that work from the ranks of journalism, not from business. But the ability to write anything well consists principally of natural aptitude. Training is of less importance and is useless without the first qualification. The saying, "Poets are born, not made," is almost equally true of other writers. This sounds as though the chemist could not hope to write effective advertisements for himself. I do not think that is so. In the first place, it is impossible to write upon any subject without knowing something about it. and pharmacy is a difficult subject for an outsider to master. Secondly, the services of the really good men in the advertising business are not available for small retail shopkeepers in our business or any other. They are nearly all employed by the big agents and engaged upon the work of advertisers who are spending many thousands a year. I have seen the work of some of the self-styled experts, who offer their services to the drug trade, and I am convinced that the average chemist could produce better copy than anything I have seen from them.

Good Writing. I propose first to consider some of the ideals of good writing in general, and then to discuss their application to advertisement writing. You must remember that in writing you are setting the reader a task—to grasp, put together, and consider the thought you are expressing. You can make that task easy or difficult. Just take up in imagination a good but difficult novel of the Victorian period, and a bad but popular one published last year. You may find the former tires you if you are not very eager to read it, while the latter you can go on reading in spite of a gradually developing contempt. The reason is that the newer novel possesses the quality known as "readableness." You will see at once that this quality is absolutely essential in advertisement writing. The man who is reading a novel or a text-book may tolerate a style lacking this merit, because he hopes to enjoy or profit by his reading. But if he is reading an advertisement he has no particular desire to go on; he has only begun because

* Read before the North London Pharmacists' Association.

you have tricked him into doing so by means of a catchy headline or in some other way.

To write clearly you must have, first, a clear idea of what you want to say. Second, you must present your thoughts accurately and briefly, yet completely, and with a sense of proportion, emphasizing if possible what is most important. And you must avoid certain faults which will be likely to distract or confuse the reader. It is to the third requirement that I wish particularly to direct your attention. Suppose, for example, you drag in something that does not matter and does not help your argument. The reader may neglect your argument to consider it. Or, if you make a grammatical error or use a wrong expression, he will stop to criticise it. In either case, his mind is diverted from your argument to something else, and he does not grasp your meaning with the same clearness as if nothing had occurred to withdraw his attention.

Faults in Writing. The chief faults of a bad writer are—using words without considering their exact meaning, using too long sentences, and straining after effect. Some people write without thinking, using stock words and phrases. One of the worst offenders is, strange to say, a professional writer—the inferior journalist. With him a fire is a “devastating conflagration,” an oyster is a “succulent bivalve,” every funeral is a “solemn cortege,” and a pathetic incident is always either a “touching” or a “heartrending” scene. It was a man of this type who announced the death of a celebrity as having occurred after a “short but protracted illness.” Other expressions that would be avoided by thinking what a word means before writing it are “cheap prices,” “very moderate,” “very exceptional,” “unqualified pharmacist.” It is best for a writer who is not sure of his literary skill to use short sentences. There is far less risk of confusing himself and the reader. Always in advertisement writing I would recommend short sentences. Many short sentences following each other have a bad effect sometimes, but only in long compositions.

It is curious how a business man will write a dozen business letters in good English, and then write something for publication containing gross blunders. The reason is that he tries to be clever. I will not say, “Don’t try to be clever,” because if nobody tried to be clever probably nobody would be, and the world would be poorer. But the only cleverness desirable in writing is that which increases the clearness, force, or beauty of what you write.

A common fault in writing is to use too many words. This is called in different cases circumlocution, verbosity, tautology, and pleonasm. Circumlocution is an elaborate statement where a shorter, simpler one would convey the meaning quite as fully. All writing is a compromise between brevity and completeness; circumlocution errs on the side of the completeness. That sounds as though it were a good fault, but it is not; it is one of the worst. If you announce that your purse and money have been stolen, there is no need to mention that the money was in the purse. Legal language is often circumlocutory, but no doubt that is necessary. Verbosity is a form of circumlocution in which pompous language, out of proportion to the subject, is used. Sometimes circumlocution has a rhetorical or a humorous intention, in which cases it is justifiable. A schoolmaster once said to a boy who had left his study door open, “Let the

guardian of our secrets revolve upon its hinges." Tautology is where the same meaning is conveyed twice in different words; for example: It will cure your cough and drive it away. Pleonasm is the fault of including words in a sentence where the sense is complete without them, as in "They are both alike," "This is the better of the two." Pleonasm is often justifiable; it may make the meaning clearer. But in general superfluity is a bad fault in writing. Try to be as concise as possible. We can all think faster than we can read or speak; therefore, reading and speaking always delay thought. Superfluity delays it still more. That is why pictures are of such great value in advertising. A picture will convey in half a second what could not be conveyed in words in less than half a minute.

Slang to be Avoided. The word barbarism is used to indicate various outrages upon the language. Some would say that all slang is barbarism. I do not agree, but one must be very careful about slang. Consider the character of your composition before deciding to use a slang expression. Slang is inimical to dignity, but it may give vividness and force to a sentence. In general I would not use slang in advertisements. The ordinary writer must remember that he is not entitled to coin words; he must take the language as he finds it. Personally, I regard the use, by English business men of American business jargon, as barbarism—"loan" for "lend," "mail" for "post," "carry" for "kept in stock." "Gent." is an abomination of which tailors are very fond; also I do not like "Xmas" for "Christmas," though it may be used sometimes. A few days ago I saw the word "expensiveless," I hope I shall never see it again. Metaphors and metaphorical expressions are so common and add so much to the vividness of language that we use them every minute of the day. To say "see," and "feel," for "understand" and "think," is metaphorical. Metaphor brings an image to the mind, and the metaphor is bad if that image is a grotesque one. It is also bad if the metaphorical meaning can be confused with the literal one. To say, "He made a fatal mistake in the Minor," is a metaphorical use of the word "fatal," and quite a proper expression. But, "It is fatal to take a baby up every time it cries," is a bad use of the same metaphorical expression.

Ambiguity is another common fault. It often arises from incorrect or omitted punctuation. "William said John is a fool," is ambiguous; it requires either one or two commas. Ambiguity may also arise through putting a qualifying clause in such a position that it appears to refer to the wrong word. "Room to let for single gentleman, fifteen feet by ten." The woman who advertised, "Respectable woman wants washing," may have announced a fact without intending it. The commonest form of ambiguity arises in the use of pronouns. "He said that if he did that again, he would dismiss him at once," is quite clear, but it is an accepted rule that such sentences should not be written. Pronouns must not be used in such a way that the reader has to sort them out, as it were, and study the context to find their antecedents.

Anacoluthon is beginning a sentence in one grammatical form, and finishing it in another. "A hot-water bottle will make you nice and cozy and ensures sound refreshing sleep." Two verbs occurring like that must agree in tense. In this connection I would mention that a short composition must not be written

alternately in the first and the third persons. You must not say, "John Jones has opened the above premises," and later, "I keep only the best and purest drugs." Nowadays the first person is generally preferred for such announcements, but whichever you choose you must keep to it for that announcement. Solecism is the kind of mistake foreigners make. It is the mistake of a writer who knows a language but is inexperienced in the use of it. There are rules which we all observe, but none of us can quote, called Rules of Syntax. They direct us how to make our sentences; we master these rules in childhood without learning them. Solecism can generally be detected at once. We should say, "It sounds wrong," and perhaps the only explanation we could give would be, "We don't say that." Well! that is good enough. A living language is what the people speak, established more by custom than by rule. Remember that writing is subordinate to speaking. That brings us to a golden rule—when you have written anything of importance, read it aloud to see if it "sounds right." The best unskilled writers, and often the best skilled ones, are those who write just as they would speak.

I am not going to deal at great length with the merits of good composition. Most of the points I might be inclined to dwell upon make for elegance rather than force and clearness, and it is the latter qualities that are wanted in advertising. But in all writing, one quality is needed—judgment to decide what is, and what is not, worth saying, considering the object in view. Many a good idea is rejected because it will not be effective as an advertisement. I have seen advertisements containing philosophical reflections. They are not wanted. Get to the point quickly, and save the printer's ink you have paid for, and the time the reader values.

The Choice of Words. And the next great essential in advertisement writing is the habit of choosing the most vivid language possible, without overstepping the border line between sense and absurdity. Short words are more vivid than long ones, specific terms are more vivid than general terms, concrete terms are more vivid than abstract terms, definite terms are more vivid than indefinite terms. Metaphor and simile give vividness. "Icy wind" is more vivid than "cold wind." "Hard as a rock" is more vivid than "very hard." Just compare these as I repeat them: Sank rapidly, sank quickly, sank at once, sank like a stone, sank like lead. The last two are most vivid, because the idea is conveyed in concrete terms. Of the others, you would prefer "sank quickly." I will tell you why in a moment. Now compare these: Has cured many, cures everybody who tries it, has cured thousands. The last is most vivid and therefore best, because it is definite, in spite of the fact that the second makes a more sweeping claim. Again compare: "Relieves all distressing symptoms," with "cures the nasty headache and the disagreeable giddy feeling." The second is better because it is specific.

Even among words which are not figurative some are more vivid than others. Onomatopoetic words, that is words which are an approximate representation of sounds or things they indicate, are the best examples of vivid words—crash, bang, whistle, tinkle, crackle, whine, howl, chatter. Below these, in the scale of vividness, are many words which seem to have at least some sympathy with

their meaning—quick, slow, mournful, terrible, horrible, enormous, tremendous, magnificent, tiny, rush, dash, rattle. All these are vivid because the sound, as well as the meaning conveys the thought expressed. Now consider the little word “very.” It may be described as a word that has failed. It is the reverse of vivid, and it has had its punishment. In every age, probably, we have put aside this little word with a big meaning in favor of something else. Today the substitutes are “awfully” and “beastly,” ugly but vivid words. In the eighteenth century, “vastly” was, I believe, the favorite pseudo-synonym.

How to Secure Attention. An ordinary advertisement has to do three things in succession. First, to secure attention; second, to argue its case; and, third, to give the information the reader will require if he intends to respond. There are many ways of securing attention, but the commonest, and one of the best, is by means of a “striking” headline, which would be better called a “catchy” or “interesting” headline. The inferior advertisement-writer seems to think that any three or four words in big type is a good headline, but a really good headline must be interesting, it must promise to talk about something that will interest the reader. This is where the journalist excels, for it is part of his training to value news items according to their interest. Here are a few of the commonest interests. General—humanity, news, topical, puzzling, humorous. Masculine—success, politics, sport. Feminine—personal adornment, children, domestic affairs. There are also special interests as, for example, a person suffering from rheumatism is interested in that complaint. Now if your headline contains such words as, let us say, man, woman, girl, child, sensation, amusing, mystery, money, fortune, football, golf, beauty, baby, home, or if it contains a reference to some political or other event of the moment, it will catch the eye of hundreds of people as they glance over the paper. Unconsciously they will read on and so get your message. If the argument is a good one, and it appeals to their want, there is a chance that business may result. Now for the argument. Deal briefly and as vigorously as you can with the point or points most likely to appeal to the reader. Don’t spoil things by trying to say everything that can be said. And, in choosing those points, the chemist, working day by day at his own counter, has an immense advantage over the professional advertisement writer. Note what questions the public ask, when you push your own specialties at the counter. Finally, don’t leave the reader without the information he will want if he is going to respond to your advertisement—name of article, price, and your name and address.

The best advertisements of all are those which appeal to the imagination, because the writer makes use of the reader’s brain, and, by means of, perhaps, a dozen words, causes the latter to think out an argument that could not be conveyed in less than a hundred. “Good morning, have you used Pears’ Soap?” is, I consider, the finest advertisement in the English language. It makes use of the reader’s brain, though not quite in the way I have indicated. Here is an example of what I mean. As an apprentice I used to pass a shop bearing the legend, “Where Maggie got her home for £6.” Think of the tremendous effect that sign would have upon the working-class couple who were prepared to spend, say, £12. They would feel that they were in a position to furnish a

palace—that they had got £6 to spare for luxuries—things that Maggie who, none the less, got a complete home, had to go without.

I have brought with me a few instructive advertisements which I will show you, and we will consider their points. One thing you will gather is this—if you want to learn how to advertise, study the advertisement columns of papers where space is expensive; if you want to see how not to do it turn to those papers where you can get about six inches of double column for a sovereign.—*Pharm. Jour. and Pharmacist (London.)*

THE INTELLECTUAL LIFE OF AMERICA.

While the sum total of American intelligence is undoubtedly impressive, it is more by reason of its quantity than its quality. I mean that the educational system of the country has rather raised a great and unprecedented number of people to the standard of what we in England should call middle-class opinion than raised the standard itself, and that as a consequence the operative force of American politics is middle-class opinion left pretty much to its own devices and not corrected by the best intelligence of the country. And middle-class opinion, especially when left to its own devices, is a fearsome thing. It marks out the nation over which it has gained control as a willing slave of words, a willing follower of the fatal short-cut, a prey to caprice, unreasoning sentiment and the attraction of “panaceas,” and stamps broadly upon its face the hall-mark of an honestly unconscious parochialism. Such, to be quite candid, appears to me to have been too much its effect in America. I know of no country where a prejudice lives so long, where thought is at once so active and so shallow and a praiseworthy curiosity so little guided by fixed standards, where a craze finds readier acceptance, where policies that are opposed to all human experience or contradicted by the most elementary facts of social or economic conditions stands a better chance of captivating the populace, or where men fundamentally insignificant attain to such quaintly authoritative prestige.—*Sydney Brooks.*

Of General Interest

MINUTES OF A MEETING OF THE EXECUTIVE COMMITTEE OF THE NATIONAL DRUG TRADE CONFERENCE HELD AT THE NEW WILLARD HOTEL, WASHINGTON, D. C., WEDNESDAY, MARCH 18, 1914.

The Executive Committee of the National Drug Trade Conference met in the Gridiron Room of the New Willard Hotel, pursuant to the call of the President of the Conference, Wednesday, March 18, 1914, at 10 o'clock a. m.

Present: All the members of the Committee.

Mr. John C. Wallace and Mr. Chas. M. Woodruff were, respectively, unanimously chosen Chairman and Secretary of the Committee.

The minutes of the last meeting of the Committee as printed were approved without reading.

On motion of Prof. Jas. H. Beal the Committee proceeded to consider the Harrison Bill as amended by the Finance Committee of the Senate and on the Senate Calendar under No. 213, Report No. 258. The following amendments were duly recommended:

Page 1, line 1. Make "January" read "October."

Page 2, lines 1, 2 and '3. Strike out the words "or hypodermic syringes or needles adapted to administer any of the above drugs," or else insert the words "except veterinary hypodermic syringes and needles, and hypodermic syringes and needles designed and used for the administration of serums, vaccines, toxins and analogous products."

Page 2, lines 12 and 16: If the hypodermic syringe provision is stricken out, then strike out the words "or articles."

Page 2, line 18: Note typographical error in the word "provided."

Page 2, lines 20, 21, 22, 23, 24, and page 3, lines 1 and 2: "Strike out all after the word "section" in line 20 to the end of the paragraph on page 3, line 2, and insert in lieu thereof the following:

"Provided, further, that officers of the United States Government who are lawfully engaged in making purchases of the above named drugs [and articles] for the various Departments of the Army and Navy and for government hospitals and prisons, and officers of any state government, or of any county or municipality therein, who are lawfully engaged in making purchases of the above named drugs or articles for state, county or municipal hospitals or prisons and officials of any territory or insular possession of the United States who are lawfully engaged in making purchases of the above named drugs for hospitals or prisons therein shall not be required to register and pay the special tax as herein required."

Page 3, line 3: Insert after the word "person" the words "obliged to register under the terms of this Act." The Act requires *every one* having anything to

do with the production, manufacture, sale, giving away or dispensing, to register and then excepts certain officers of the Federal and State Governments.

Page 3, lines 5 and 21: "If the hypodermic syringe provision is stricken out, then strike out the words "or articles."

Page 4, lines 1 and 2, also line 9: If the hypodermic syringe provision is stricken out, then strike out the words "or articles."

Page 4, line 19: If the hypodermic syringe provision is *not* stricken out insert the words "or articles" after the words "drugs."

Page 5, lines 6 and 7: Strike out the words "registered under this Act."

Page 5, line 2. After the word Act add the following provision:

"Provided also that a record of the drugs thus dispensed shall be made in a suitable book kept for that purpose, and shall be preserved for two years in such a way as to be readily accessible to inspection by the officers, agents, employees and officials hereinbefore mentioned."

Page 5, lines 4 and 17: If the hypodermic syringe provision is *not* eliminated insert the words "or articles" after the word "drugs."

Page 5, lines 5 and 10: Make the word "pharmacist" read "dealer."

Page 5, line 11: Strike out the letter "s" in the word "prescriptions."

Page 5, line 12: Make the words "each prescription" read "the same."

Page 5, after subsection (c) add the following:

"(d) To the sale, barter, exchange or giving away of any of the aforesaid drugs (or articles) to any officer of the United States Government or any state, county or municipal government lawfully engaged in making purchases thereof for the various departments of the Army and Navy, and for government, state, county or municipal hospitals or prisons."

Page 6, line 23: If the hypodermic syringe provision is eliminated strike out the words "or articles."

Page 7, line 5: If the hypodermic syringe provision is eliminated make the word "articles" read "drugs"; if not, insert the words "drugs or" after the word "said."

Page 7, lines 1, 3, 11 and 21: If the hypodermic syringe provision is eliminated strike out the words in italics.

Page 7: Insert after the first paragraph and between lines 5 and 6 the following:

"The provisions of this Act shall apply to the United States of America, the District of Columbia, the District of Alaska, the Territory of Hawaii, the Insular Possessions of the United States, and the Canal Zone. In Porto Rico and the Philippine Islands the administration of this Act, the collection of said special tax, and the issuance of the order forms specified in Section 2, shall be performed by the appropriate internal revenue officers of those governments, and all revenues collected hereunder in Porto Rico and the Philippine Islands shall accrue intact to the general governments thereof, respectively. The courts of first instance in the Philippine Islands shall possess and exercise jurisdiction in all cases arising under this Act in said Islands. In the Canal Zone, the administration of this Act, the collection of the said special tax, and the issuance of the order forms specified in Section 2, shall be performed by such officer or officers in said Canal Zone as the President may designate for that purpose. The courts of the Canal Zone having jurisdiction of crimes and offenses committed

in said Zone shall have jurisdiction to hear, try, and determine all actions and proceedings in which any person shall be charged with having violated any of the provisions of this Act within the limits of said Canal Zone."

Page 8, lines 2 and 24: If the hypodermic syringe provision is eliminated strike out the words "or articles."

Page 8, lines 5 to 11 inclusive: Strike out all after the word "Act" to the end of the section and insert in lieu thereof:

" , or to any person who shall deliver any such drug or article which has been prescribed or dispensed by a physician, dentist or veterinarian who has been specially employed to prescribe for the particular patient receiving such drug or article."

Page 10, line 5: Make the word "one-twelfth" read "one-fourth."

Page 10, lines 16, 17 and 18: Strike out the provision reading: "Provided, that the amount of any drug herein mentioned shall be shown upon the label of the container of such remedy or preparation."

Page 11, lines 7 and 8: If the hypodermic syringe provision is eliminated strike out the words "or articles."

Page 11, line 12: After the word "person" insert the words "or to a nurse under the supervision of a physician, dentist, or veterinary surgeon registered under this Act." *This amendment will not be necessary if the hypodermic syringe provision is stricken out of the Act.*

Page 11, line 13: If the hypodermic syringe provision is *not* stricken out of the Act insert the words "or occupation" after the word employment.

Page 11, lines 14 and 18: If the hypodermic syringe provision is *not* stricken out insert the words "or articles" after the word drugs.

The Conference then took a recess for lunch and re-convened about 2:30 p. m.

On motion a number of bills which had been referred to the Executive Committee by the last Conference (see page 9, Proceedings of the National Drug Trade Conference held January 13, 1914), were referred to a special committee consisting of Prof. Jas. H. Beal, C. Mahlon Kline and Chas. M. Woodruff, with instructions to prepare briefs to be submitted to the chairman of the proper congressional committee after they had been first submitted to and approved by the members of the Executive Committee.

On motion, duly seconded, put to vote and carried, the Secretary was requested to inquire of the Chairman of the Committee on Revision of the United States Pharmacopœia what probable action would be taken by the Revision Committee in the way of adopting standards of shapes, colors, etc., of Mercury Bichloride tablets.

On motion of Prof. Jas. H. Beal, duly seconded, put and carried, the Secretary, Dr. A. R. Dohme and Dr. J. C. Stover were appointed a special committee to interview the proper authorities of the Postoffice Department respecting some law or regulation that would permit the mailing of medicinal preparations containing poisons; and that the Committee be authorized to use discretion in pressing an early settlement of the question.

Bill H. R. 13305 was then read, and on motion duly seconded, put and carried, the Secretary was instructed to inform the Chairman of the House Committee to

which it was referred that the Executive Committee of the National Drug Trade Conference favored the principle of price standardization involved in the measure, although the Committee was not prepared to express an opinion upon the bill in all its details.

A communication was then read asking that the Conference endorse the following resolution:

"Resolved, That the National Food Trades Conference does hereby recommend the appointment of a competent Federal Commission by the President by and with the consent of Congress authorized and directed to investigate the pure food and drugs laws of such foreign nations as may appear most advisable, and their administration and enforcement and to report fully the result of such investigation, which report shall include a statement of the existing laws, regulations, standards, methods and such other information as may be of interest, which report shall be published and made available for general use."

On motion duly seconded, put to vote and carried the resolution was received and referred to the Conference.

On motion, duly seconded, put to vote and carried, Dr. A. R. L. Dohme was requested to confer with the Revision Committee of the National Formulary and induce them to reduce the quantity of heroin in official mixtures from one-third to one-quarter grain per fluidounce.

There being no further business to consider, the Committee adjourned.

CHARLES M. WOODRUFF, Secretary.

KNOW WHAT YOU WANT—THEN GO AFTER IT.

"Half the failures, half the fellows who never get beyond holding down an unimportant job at only a small salary," said an employer of many men the other day, "have quite as good brains and education as the chap who goes by them like an express train past a post. Only he knows exactly what he wants, and goes after it with all there is in him. You can't stop the one kind—and you can't boost the other."

How about you? Do you know what you want?

If you do know, thoroughly and clearly, and want it hard enough, you'll get it. Or at least you'll come mighty close to getting it, and you'll certainly be one of the movers, not one of the stickers in life.

If you know what you want you won't be haphazard in your aims, and your energies will be directed into a single channel. There won't be what efficiency experts call "waste movements."

Try then, right away, to arrive at a clear understanding of what you want. After that study out the steps necessary to get it and begin on the nearest one.

You will be more than astonished to find how this distinct knowledge helps—how the things you do begin to count, how the waste wood is cleared out and the trail you mean to follow grows plainer.—*The Western Druggist.*

The Bulletin Board

SECTION ON EDUCATION AND LEGISLATION.

To the Members of the American Pharmaceutical Association:

It is desirable that at the 1914 convention of the Association there be provided for the Section on Education and Legislation a program of papers and discussions that will be commensurate with the importance of this division of the organization. The chairman therefore would ask that the members, not only those who are interested directly in educational and legislative matters, but particularly the practicing retail pharmacist who is directly affected by all conditions arising under educational and legislative practices, to contribute papers for the section or to acquaint him of their willingness to participate in the discussion of topics of general interest.

In this connection he wishes to offer the following topics as of general interest:

1. The comparative real and permanent benefits to the student of laboratory work and lectures.
2. The comparative advantages of practical experience and general education as a prerequisite of instruction in a college of pharmacy.
3. The advantages of the Association itself formulating standards for pharmaceutical teaching institutions and pharmacal examining boards.
4. The necessity for getting representation of the various interests embraced by the Association in the consideration of legislation.

It is not the intention of the chairman to limit papers or discussions to these topics, as he quite well recognizes the variety of subjects that may well be brought before the section.

Very truly yours,

HUGH CRAIG.

THE WOMEN'S PHARMACEUTICAL ASSOCIATION.

The regular monthly meeting of the Women's Pharmaceutical Association of the Pacific Coast was held in the assembly hall, Pacific building, San Francisco, March 27,

1914. Mrs. R. E. White, the president, was in the chair.

Difficulties in spreading asafetida plasters; syrup of hypophosphites and syrup of hypophosphites comp., acetic acid in eye drops, London purple and taka-diatase were discussed during the roll call.

Mrs. White had a very carefully prepared paper on various methods of preparing cold cream and samples of U. S. P., G. P. and B. P. cold creams. Miss Roehr read a paper prepared by Mrs. Rees on "Ventilation in Drug Stores." The discussion of the evening was on the proposed Recipe Book of the American Pharmaceutical Association and was opened by Dr. Winslow, followed by Mrs. White, Mrs. Kane and Miss Roehr.

The next meeting of the Association will be held in San Francisco, April 24, 1914.

UNIVERSITY OF ILLINOIS SCHOOL OF PHARMACY.

The 54th commencement of the University of Illinois School of Pharmacy (Chicago College of Pharmacy) was held at Howard's theatre, Chicago, on Wednesday afternoon, April 22. The principal address was made by Prof. John Uri Lloyd on the subject, "The Young Pharmacist's Opportunity." President Edmund J. James, of the University of Illinois, conferred the degree of Graduate in Pharmacy upon a class of thirty-three candidates as follows: Albert F. Anderson, St. Johns, Ariz.; Edna Becker, Davenport, Ia.; August C. Bosch, Gratiot, Wis.; J. Burdette Brown, Tampico, Ill.; Floyd W. Bryant, Elizabeth, Ill.; George E. Canham, Neponset, Ill.; Lawrence Converse, Chicago; Walter A. Endee, Chicago; Oscar Fisler, Chicago; Jeremiah G. Garrity, Spring Valley, Ill.; Harry F. Haines, Farmer City, Ill.; Philip I. Hildebrandt, Lake Mills, Wis.; Elwood J. Hollinshead, Morrisson, Ill.; Harry E. Johnson, Rockford, Ill.; Jonathan G. Jordan, Chicago; Elmer C. Lane, Kankakee, Ill.; Paul I. Mendelsohn, Chicago; Richard W. Merschat, Chicago; Abraham Myerson, Chicago; Charles C. Orr, Chicago; Irving F. Pearce, Chicago; Elmer E. Rueckert, Lake Mills, Wis.; Harold Schmid, Chicago; Ralph H. Thompson, Earlville, Ill.; Adrian Ton, Chicago; Clio Vavra, Chicago; Ladislaus J. Warzynski, Chicago; Albert J. Cook, class of '13, Terre Haute, Ind.; George C. Kraemer,

class of '13, Chicago; Wm. A. Lee, class of '13, Chicago; Alva W. Rackaway, class of '13, Mt. Vernon, Ill.; Chas. F. Wach, class of '13, Chicago; Mary L. Smith, class of '09, Dallas City, Ill.

Seven others received certificates as follows: Paul W. Edgett, Earlville, Ill.; Hubert S. Huston, Carthage, Ill.; Gennaro D. Lavieri, Chicago; Fred L. Leib, Anna, Ill.; Albert Schreiner, Batavia, Ill.; Frank J. Vondrasek, Chicago; George Vaupell, Chicago.

Prizes were awarded as follows: The Becker prize, Jeremiah G. Garrity; the Herman Fry prize, Miss Edna Becker; the faculty prizes, consisting of A. Ph. A. memberships: in materia medica, Albert Anderson; in pharmacy, Albert Schreiner, Jr.; in chemistry, George Vaupell.

In the evening the Alumni Association held its annual reception and banquet at the Congress hotel. The members of the graduating class were the guests of the evening. A feature was the reunion of the class of 1889, which celebrated its 25th anniversary. Toasts were responded to by President Edmund J. James, of the University; Mr. L. L. Abbott, of the board of trustees; Mr. George P. Mills, President of the Alumni Association; Acting Dean W. B. Day; Mr. Wm. A. Converse, of the class of '89, and Mr. Ralph Thompson, President of the class of '14. Professor A. H. Clark presided as toastmaster. About 150 of the alumni and their friends attended.

COMMENCEMENT OF THE ATLANTA COLLEGE OF PHARMACY.

The commencement of the Atlanta College of Pharmacy for the class of 1913-14 took place at the Atlanta theater on the evening of March 30, and in spite of a tremendous downpour of rain during the day and night, there was an excellent attendance. There were forty-two graduates who took the degree of Ph. G., and two who took the degree of Ph. C. All the exercises of the evening were carried out by the faculty and the students without any assistance from outside speakers. Mr. William Tee Morgan, of Alabama, was the salutatorian; Mr. S. C. Davis, of North Carolina, the historian; Mr. R. C. Powell, of Georgia, the poet, and Mr. S. C. Moon, of Georgia, the valedictorian. All four

acquitted themselves in a most excellent manner. The degrees were conferred by the president and the professors, five out of the six professors are licensed pharmacists as well as graduates in pharmacy; all of them have been successful in the drug business. The attendance of the college during the past college year has been made up by students from every state from North Carolina to Texas and west to Arkansas, with a good sprinkling of Cubans.

UNIVERSITY OF THE STATE OF NEW JERSEY.

DEPARTMENT OF PHARMACY.

A series of lectures is given at the College of Pharmacy of the University of the State of New Jersey, which is located at 96 Summit Ave., corner Clifton Place, Jersey City.

The third of these lectures was given Friday, January 30, in the lecture room of the college. The subject was, *Preparation, Sterilization, Preservation and General Uses of Modern Vaccines and Anti-Sera*. The lecturer was Dr. Max Lederer, Pathologist to the Jewish Hospital of Brooklyn, who is a man of reputation and who is well known in medical as well as pharmaceutical circles.

The lecture was well attended by the faculty and the students of the college as well as by pharmacists and physicians of Jersey City.

These lectures will be continued throughout the winter and will deal with subjects of interest to the pharmaceutical and medical profession.

ALUMNI ASSOCIATION OF THE MASSACHUSETTS COLLEGE OF PHARMACY.

At the annual meeting of the above association held at the College Building in February, the following officers were elected for the ensuing year:

President—Prof. E. H. LaPierre.

Vice Presidents—R. Albro Newton, G. W. Russell, T. J. Connors.

Secretary—John D. Glancy.

Treasurer—Leon A. Thompson.

Auditor—Harold Jenness.

Council—Frank Piper, A. W. Balch, T. J. O'Brien, C. E. Tracy and Paul C. Klein.

JAMES H. BEAL, Editor.....Scio, Ohio

ERNEST C. MARSHALL, Associate Editor,
63 Clinton Building, Columbus, Ohio

All communications for insertion in the JOURNAL, or respecting advertising should be sent to the Editor.

The Association does not accept responsibility for the opinions of contributors. Offensive personalities must be avoided.

Under the rules of the Postoffice the JOURNAL can be regularly mailed only to bona-fide paid subscribers. Subscriptions and association dues should be sent to the Treasurer, H. M. Whelpley, 2342 Albion Place, St. Louis, Mo.

Requests for back numbers, and claims for missing numbers should be sent to the Editor.

Claims for missing numbers will not be allowed if sufficient notice has not been given of change of address, and in no case if received later than sixty days from the date of issue

REPRINTS.

If the request is made at the time copy is submitted, authors will be furnished with not to exceed 50 reprints, without cover, of papers accepted for publication in the JOURNAL.

Larger numbers of reprints will be supplied by the Stoneman Press Co. at the following prices, provided the order is received before the type has been distributed:

100 copies, 4 pages, no cover, \$2.50, with cover, \$4.50.

200 copies, 4 pages, no cover, \$3.00, with cover, \$5.50.

50 copies, 8 pages, no cover, \$2.75, with cover, \$4.50.

100 copies, 8 pages, no cover, \$3.50, with cover, \$5.00.

200 copies, 8 pages, no cover, \$4.50, with cover, \$6.50.

50 copies, 12 or 16 pages, no cover, \$4.00, with cover, \$5.50.

100 copies, 12 or 16 pages, no cover, \$5.00, with cover, \$6.50.

200 copies, 12 or 16 pages, no cover, \$6.50, with cover, \$8.00.

Orders for reprints may be sent either to the Editor, or to the Stoneman Press Co., Columbus, Ohio.

WHY NOT?

One of the most enthusiastic A. Ph. A. workers sends this to the Editor, and the latter takes pleasure in passing it on to the officers and members:

Why not put these questions to every officer and committeeman of the A. Ph. A.?

1. What are you doing for the American Pharmaceutical Association?

2. Do you contribute any original papers?

3. Do you take an active part in the proceedings of your nearest branch?

4. Do you tell your medical and pharmaceutical friends what it means to be a member of this great organization?

5. Do you think it just to ask for further recognition without giving anything in return?

6. Why not get busy at once; you may be required to give an accounting at the Detroit meeting?

ADDITIONAL PRIZE MEMBERSHIPS.

It will no doubt interest the members to learn that two prizes of nominations to memberships in the Association are offered in the Department of Pharmacy of the University of the State of New Jersey.

One is offered by Prof. J. Leon Lascoff, Professor of Pharmacy, and is to be given to the post-graduate student writing the best thesis on a pharmaceutical subject; the other is offered by Prof. Otto Raubenheimer, Professor of Pharmaceutical Chemistry and the History of Pharmacy and Chemistry, and is to be awarded to the post-graduate student writing the best thesis on a chemical subject.

STATEMENT OF OWNERSHIP, MANAGEMENT, ETC.

Of the JOURNAL OF THE AMERICAN PHARMACEUTICAL ASSOCIATION, published at Columbus, Ohio.

Editor—J. H. BEAL, Scio, Ohio.

Managing Editor—J. H. BEAL, Scio, Ohio.

Business Manager—J. H. BEAL, Scio, Ohio.

Publisher—American Pharmaceutical Association, Office at Scio, Ohio.

Owners—The American Pharmaceutical Association, Office, Scio, Ohio.

Is a corporation not for profit, incorporated under U. S. Laws at Washington, D. C., and does not have a capital stock.

Known bondholders, mortgagees, and other

security holders, holding 1 percent or more of total amount of bonds, mortgages, or other securities: None.

(Signed) J. H. BEAL, Editor.

Sworn to and subscribed before me this 28th day of March, 1914.

(Seal) HARRY A. ECKMAN,
Notary Public.

(My commission expires Jan. 10, 1916.)

BEWARE OF SUIT-CASE PEDDLERS.

Druggists should beware of suit-case peddlers who sell manufacturers' products at attractively low rates—lower usually than those at which even the jobber can buy. If it should appear that pharmaceuticals so purchased had been stolen, and if the druggist purchasing them should be complained of for receiving stolen property, it would be difficult to convince a jury that the circumstances had not put the druggist upon his inquiry and that the druggist had purchased in good faith. Irregular brokers are being watched by manufacturers and wholesalers who have been the victims of systematic robbery.

According to Kansas City journals, Grover Buckland, 28 years old, an employee of the McPike Drug Company, has been arrested, tried, convicted, and sentenced to a year in the penitentiary for theft of opium, morphine, etc., from his employer. The thefts were systematic and continuous; but, of course, conviction was upon a single instance. Buckland about three years ago was discharged from the Kansas City office of Parke, Davis & Co. on account of pilfering. Buckland's output was through one Miller, who is yet to be dealt with.

SCALES AND WEIGHTS.

The first step in, what is said to be, a nation-wide attempt to secure greater accuracy in the scales in use in drug-stores has been taken in Massachusetts, where the State Commissioner of Weights and Measures has directed his deputies to inspect the scales and weights used in the preparation of prescriptions, as well as those used in the sales of articles by the ounce and pound.

The Commissioner says:

"I have not yet secured many official and signed reports from the various sealers who are making this investigation. Their informal reports indicate conditions that will need extensive improvement. I am not prepared to

say what percentage of scales will be found to be defective, but there is little doubt that hundreds of scales will have to be seized.

"The point that to me has seemed most important is that the customer who goes to a drug store with a prescription to be compounded must expect that absolute accuracy shall be guaranteed by the fact that he is dealing with a competent pharmacist. Yet competent pharmacists may queer the remedies prescribed by the physician if their scales are even slightly off. The doctors expect that the ingredients of a prescription will be combined in exact proportions. It is of great importance that they shall be so combined. If the scales prevent such accuracy, the results are likely to be unfortunate in almost all cases, and it is quite conceivable that in some cases they might be serious. Lives in fact may be jeopardized.

"This to me is far more important than other aspects of the situation. The percentage of loss to the customer is likely to be small. He will not pay for any large amount of merchandise which he does not receive. Apothecaries' scales are delicate things. There is a vast difference between weighing drugs and zinc or potatoes. Quantities are smaller. The customer's gain or loss will be relatively smaller. But it is also to be considered that drugs usually cost more than potatoes."

That there is need for such inspection is shown in a paper read before the Washington Branch of the A. Ph. A. which was published in the April issue of THE JOURNAL, under the title of "The Laboratory Equipment of the Pharmacist," in which it was stated that one pharmacist of that city uses a prescription-balance composed in part of string and that a drachm weight in actual use weighed 71.6 grains.

If such a state of affairs exists in the Capital City of the nation, it would seem to indicate an imperative need for some general action to ensure more care and attention to be given to the very essentials of the correct and precise preparation of medicinal preparations. In Fitchburg and in Worcester, Mass., many scales have been reported as inaccurate, and in one small town it was reported that in all the stores inaccurate scales were found and in one of these stores all the scales were condemned.

The heart of a drug store may be said to be its scales and balances,—not its cash register,—and a condition which would not be tolerated in the latter should not be permitted to exist in the former, and it is to be regretted that it should require official action to ensure the correct doing of things which should be a matter of course in every drug store worthy of the name.

Proceedings of the Local Branches

"All papers presented to the Association and its branches shall become the property of the Association, with the understanding that they are not to be published in any other publication than those of the Association, except by consent of the Committee on Publication."—By-Laws, Chapter X, Art. III.

Reports of the meetings of the Local Branches should be mailed to the editor on the day following the meeting, if possible. Minutes should be *plainly* written, or typewritten, with wide spaces between the lines. Care should be taken to give proper names correctly, and manuscript should be signed by the reporter.

SAINT LOUIS BRANCH.

The Saint Louis Branch of the American Pharmaceutical Association met in the Saint Louis College of Pharmacy on March 20, with J. A. Wilkerson presiding.

The reading of the minutes and all preliminary matters were dispensed with to give the time to the discussion of the paper. Dr. Gustav Rehfeld gave "Some Facts and Demonstrations on Lloyd's Reagent and Alcresta Alkaloids." The paper appears elsewhere in this issue. Dr. Rehfeld was extended a vote of thanks for his paper and his interest in the Branch.

The following took part in the discussion of the paper: Miss E. Kingsland, Theodore R. Schwerdtmann, Victor H. Kremmenacher, Ambrose Muller, Francis Hemm, William K. Ilhardt, Chas. H. Horton, Leo Suppan, O. J. Cloughly, J. M. Good, F. W. Sense, M. J. Noll, David S. Ralston, Paul L. Goodale, Stephen E. Ludwig, W. F. Kahre, J. A. Sanger, Edmund D. Amour, Ward H. Lee, Gustav Kring, John O'Kane, A. C. Boylston, O. L. Biebinger, Chas. E. Caspari, C. T. Buehler, Chas. Gietner, J. A. Wilkerson and J. W. Mackelden.

JULIUS C. HOESTER, Secretary.

CITY OF WASHINGTON BRANCH.

The stated March meeting of the City of Washington Branch of the American Pharmaceutical Association was held at the Na-

tional College of Pharmacy on March 18, 1914, and called to order by the President, W. S. Richardson, at 8:15 p. m. A good attendance was noted.

The first subject of the evening was "Price Standardization," by Mr. J. Leyden White. Mr. White graphically described conditions in pharmacy today and traced the origin of cut prices to monopoly. He presented House Bill 13305, a bill "to prevent discrimination in prices and to provide for publicity of prices to dealers and to the public." The history of this bill, as well as the origin of the Fair Play League, was related, and also the "ins" and "outs" of price protection.

While the reception of this bill before noted has not been overly cordial in Congress, Mr. White stated that a number of those who had radically opposed it at the outset had been won over, without the loss of any of the original supporters.

After hearing his address, the branch tendered Mr. White a vote of thanks.

Mr. Martin I. Wilbert then read a paper on "Russian Oils," wherein he gave a complete history of their origin, use in medicine, their preparation, and alleged medicinal virtues. He further invited attention to the fact that the average retailer can purchase these oils at 80 cents a gallon and bottle them himself and have a product superior to that for which he is paying 40 to 60 cents a pint under fancy names.

In the absence of Mr. S. L. Hilton, who has made extended observations of these Russian oils recently, Dr. H. E. Kalusowski read his paper, which covered his experiments with all the leading brands of oils on the market. Samples were exhibited and their merits reported. In addition, Mr. Hilton has made many experiments to produce a wholly satisfactory aromatic oil. Samples of these, thirty or more in number, were exhibited and passed among the members for inspection. The samples flavored with cardamom, natural wintergreen and the combined oils used in aromatic elixir (compound spirit of orange) attracted much favorable comment.

Following a full discussion of the matters which had been brought before the branch by the addresses made and the papers read, the branch adjourned.

The next meeting will be April 15, 1914.

HENRY B. FLOYD, Secretary.

CINCINNATI BRANCH.

Prof. John Uri Lloyd presided at the March meeting of this branch, which was held at the Lloyd Library on the tenth of the month. The report of the Secretary was read and approved, and letters were read from Hon. William Gordon and Hon. W. Gard in approval of House Bill No. 1.

Miss Lydia DeCourcy read an admirable paper entitled "Woman in Pharmacy." At its conclusion she was given a vote of thanks and it was voted to request the JOURNAL to publish the paper in full.

Mr. H. W. Jones gave a very interesting address on "Digitalis and Opium." He described the action of the active principles of digitalis, and said that the tincture was not the most efficient form in which to administer this drug; that the best form to exhibit it is the official infusion made from properly selected leaves. Speaking of opium he called attention to the variability in morphine content of different samples, and said that absorption by the drug of moisture from the air or the abstraction of water from the drug by a dry atmosphere was responsible for that variation, which was often a difference of 5 to 6 percent from normal. The drug therefore should be kept in air-tight containers and should be assayed just prior to its use in manufacturing official preparations. He described "normal opium" as having a percentage composition of morphine 12 percent, narcotine 5 percent, codeine 6 percent, meconic acid 1 percent. There was a general discussion of the paper by the members, after which Mr. C. A. Apmeyer read a paper entitled, "Notes on Heat and Temperature," in which he described the various kinds of thermometers in use, and the reasons for the selection of alcohol and mercury in their construction. He called attention to the fact that in melting ice in a capsule over heat, that the temperature remains constant to 0° C., although heat is continuously applied, until the ice is melted, and after that occurs and the liquid begins to boil, the temperature remains constant to 100° C. until the last particle of water disappears. From these facts we may reason that some relation exists between the state of aggregation of a substance and that agent which we call "heat." It was heat which liquefied the ice and it was heat which converted the water into steam, yet the temperatures remained constant to

0° C. and 100° C. A certain amount of heat is unaccounted for. What has become of it? He explained the production of heat by friction and said that an intimate relation existed between the amount of heat generated and the amount of energy expended, which connection was stated as The Law of the Correlation of Energy. We must come to the conclusion that heat is associated in some way with the condition of the molecules of which all bodies are composed. He explained the kinetic energy and the potential energy of molecules, and said that when heat was applied to a body it either increased the motion of the molecules (the kinetic energy) or made a change in the position of them (the potential energy), or it may produce both effects. When the movements of the molecules are accelerated, there occurs a rise in temperature, which can be measured by a thermometer. What is called "temperature" is the degree or intensity of the sensible heat of a body. Heat is absorbed whenever solids pass into the liquid state or when liquid bodies pass into the gaseous condition, as in the manufacture of artificial ice or in a freezing-mixture. The heat added to a body without producing increase of temperature, is absorbed in changing the relative arrangement of its molecules and is known as "latent heat." Mr. Apmeyer concluded his discourse with a discussion of the "Increase of Volume Caused by Heat," referring particularly to the expansion and contraction of gases, in which connection he quoted The Law of Charles: "If the pressure remains constant, the volume of the gas increases regularly as the temperature increases and decreases as the temperature decreases." An interesting discussion followed the reading of this paper, in which Professors Lloyd and Wetterstroem and others participated.

On account of the convention of the American Chemical Society, which was held in Cincinnati, April 6-10, the meeting was adjourned until May.

<>

NEW YORK BRANCH.

A regular meeting of the New York Branch of the American Pharmaceutical Association was held on the evening of March 9, with Dr. H. V. Army presiding.

The minutes of the previous meeting were read and approved, as was also the treasurer's report.

The membership committee introduced Dr. M. R. Smith as a new member of the local branch and parent association.

As Professor W. C. Anderson, Chairman of the Committee on Legislation, could not be present, his report was read by Dr. Joseph L. Mayer, which report reviewed such proposed legislation affecting pharmacy as was pending at Albany and Washington.

Mr. McElhenie, representative of the branch in the Council of the American Pharmaceutical Association, read a letter from G. M. Beringer, President of the A. Ph. A., favoring the adoption of the coffin-shape as the official form for tablets of mercuric chloride in the new edition of the U. S. P. He indicated that, while the Norwich Pharmacal Co. had applied for patent on this form of tablet, they would be willing to assign all rights to the A. Ph. A. Mr. McElhenie stated that he favored the acceptance of this firm's offer and indicated that he had voted accordingly.

A letter from Mr. Hugh Craig, addressed to the Council, was read, and in this letter he indicated that in his opinion it was a waste of time to endeavor to formulate a restriction as to the shape of tablets of mercuric chloride. Mr. Craig further indicated that it appeared to him that the Association should not take a hand in the manufacture of, or the supervision of the manufacture of any article of commerce.

Mr. McElhenie also read Mr. Beringer's reply to Mr. Craig's letter, in which Mr. Beringer expressed the belief that Mr. Craig had failed to grasp the real situation presented in the Council letter and stated that the question of the official shape of tablets of mercuric chloride is only one of the means of safeguarding the careless handling of the tablets, and the idea was not presented as the sole means that should be adopted. Mr. Beringer agreed with Mr. Craig that it was necessary to educate the public to the importance of exercising the proper care in the handling of all poisons.

Mr. Berger, Chairman of the Committee on Professional Relations, reported that a joint meeting of the County Medical Association and the branch would not be held during this season, but that a propaganda meeting would be held in May, at which Professor Remington would be invited to present information concerning the progress that is being made in the revision of the Pharmacopoeia.

Doctor G. C. Diekman, as Chairman of the Committee on the Progress of Pharmacy, reported in detail on a new reaction for acetyl-acetic acid in urine and the detection of albumin in urine by means of Eschbach's reagent in presence of hexamethylen-tetramine. He also called attention to the necessity of testing cod liver oil for free iodine, especially when it was to be made into a mixture with other substances. Dr. Diekman also called attention to the fact that foreign countries were not free from the misbranding evil, and cited as an example, a product offered in Germany as boranium berries, which upon examination were found to consist of a mass of sugar to which had been added phenolphthalein, oil of peppermint, and a fruit gelatin, while the name would indicate that the item offered was a berry gathered from a plant or tree. He stated that many such instances were noted in current numbers of foreign pharmaceutical publications. This report was discussed by Messrs. Diner, Raubenheimer, Weinstein, Mayer and Roemer.

The speaker of the evening was Dr. Curt P. Wimmer. His subject was "Colloids and Their Importance to Pharmacy." Little was learned of colloidal chemistry until during the past fifteen years, although true colloidal solutions have been prepared as far back as 1802, stated the speaker. He pointed out that Thomas Graham, an English scientist, made the first systematic investigation along these lines during the early sixties, but states that the present view of the nature of colloids is diametrically opposed to that of Graham, who distinguished two worlds: the crystalline and the colloid world. The present accepted view is that there is but one world, and that the colloid state can be assumed by any substance, solid or liquid, under appropriate conditions.

The speaker indicated that the invention of the ultra-microscope gave great impetus to the work on colloids. As a general definition for colloidal solutions, Dr. Wimmer stated a colloid is a solid, liquid or gaseous substance in a certain state of subdivision or dispersion, in another solid, liquid or gaseous substance. Dr. Wimmer dealt at length with the preparation of colloids and their mechanical, optical and electric properties, together with the osmotic pressure, gravity, jellyfication, coagulation, pectinization and absorption of colloidal substances. His lecture was generously illustrated by interesting experiments.

and both Dr. Wimmer and his assistant, Dr. Jeannot Horsmann, were given a vote of thanks by the branch. A discussion followed, in which Messrs. Roemer, Diner, Raubenheimer and Mayer participated.

Under the auspices of the New York Branch of the American Pharmaceutical Association a joint meeting of pharmacists and physicians will be held on the evening of May 18th at 8 o'clock at the College of Pharmacy Building, 115 West 68th St., New York City.

The subject will be "Pharmacopoeial Revision." Professor Remington, of Philadelphia, Chairman of the Committee of Revision, will lead the discussion.

It is earnestly hoped that all pharmacists in and about New York will attend this meeting and at the same time bring with them as many of their physician friends as possible.

FRANK L. MCCARTNEY, Secretary.

DENVER BRANCH.

The March meeting of the Denver Branch of the A. Ph. A. was held Tuesday evening, March 24th, at the Albany hotel. The following members were present: Messrs. E. Powers, W. T. Hover, L. A. Jeancon, H. SeCheverell, W. S. Payne, F. J. Lord, S. T. Hensel, L. L. Alkire, W. A. Hover, S. L. Bresler, W. O. Scholtz, A. W. Clark, A. Swobodia, A. C. Cole, C. J. Clayton, B. Strickland, C. H. Skinner, S. T. Kostitch, J. P. Dow, Prof. J. Seymour and F. W. Nitardy.

The meeting was called to order by President Hover about 8:15. The minutes of the February meeting were read and approved and the Secretary reported that a copy of the resolution on the Harrison bill passed last month had been forwarded to Senators Shafroth and Thomas; also that the matter of a refund to the branch of a portion of the annual dues had been taken up in the Council.

The Library Committee reported that most of the books for the library had arrived and that everything would be in shape for the formal opening for the April meeting.

Dr. S. L. Bresler read a paper entitled, "Should Our Present Pharmacy Law be Enforced or Amended?" He called attention to the objectionable elements which had crept into the profession and queried whether these could be eliminated without more precise defini-

tion by law of the terms "pharmacy" and "drug store," a precise statement of what persons shall be given the right to conduct these two establishments, and more power being granted to the Board of Pharmacy "to revoke licenses and to close pharmacies if in their discretion the store is a detriment to humanity." He was of the opinion that a stricter enforcement of the law would result in knowledge which would be of great assistance in formulating new legislation. Dr. Hensel's paper was very favorably received and was discussed by Messrs. Hensel, Hover, Clayton, Nitardy, Clark, Scholtz, SeCheverell, Cole and Clark. Secretary Nitardy called attention to the new A. Ph. A. button and received orders for twenty of the same, which he agreed to have at the next meeting.

Mr. A. W. Clark then read a very interesting paper "On Trade Conditions," which the pressure upon our columns of other matter forces us to defer printing until a later issue.

A lasting applause showed the appreciation of those present of this valuable paper.

President Hover opened the discussion by complimenting Mr. Clark for the carefully prepared paper which furnished so much food for thought. He commented on the economic waste referred to in Mr. Clark's paper in connection with the prescription departments of the small store and expressed the hope that pharmacists would co-operate to eliminate this waste by consolidation of prescription departments or such other means as might be available.

Messrs. SeCheverell, Jeancon, Clark, Hover, Hensel, Seymour and others took part in the further discussion of this subject. Mr. Jeancon brought out the value of profitable side lines and propaganda work to help out in the prescription department, especially to help reduce the stock of many proprietaries that often have to be carried. He also stated that buying new articles short from another druggist in just the quantity called for on the first one or two prescriptions had saved him much money, as in a great many instances there was no further call for an article after the first prescription.

President Hover's paper on "Bank Credit" was, on account of the lateness of the hour, deferred to the next meeting.

There being no further business the meeting adjourned.

F. W. NITARDY,
Secretary.

PITTSBURGH BRANCH.

The regular monthly meeting of the Pittsburgh Branch was held at the College of Pharmacy, Friday evening, April 17. Owing to the unavoidable absence of the secretary, Dr. Louis Saalbach recorded the proceedings. The important feature of the evening was the illustrated lecture by Dr. L. K. Darbaker on "Medicinal Plants," in the presentation of which Dr. Darbaker was ably assisted by one of the members of the Senior class of the college, Harry B. Honaker. In opening the subject Dr. Darbaker said, "The average pharmacist is not usually familiar with many of the plants which yield official drugs, and," he added, "for that reason I propose to test the knowledge of those who are present by putting into each person's hands a sheet of paper numbered to correspond with the slides as they are thrown on the screen, and will ask that each will put down his guess as to what particular plant is as it is shown without identification. I will then run the series a second time, giving the correct names of the plants, when we shall see what we shall see."

The correctness of the doctor's statement was abundantly certified to by results, as comparatively few sheets were found to bear any appreciable number of proper identifications. The pictures formed a very instructive lesson in botany, and the entertainment furnished was valuable as well as interesting. On the whole it proved a very excellent example of the very little we know of the source and origin of many drugs with which, in their commercial shape, we are very familiar, and many of which we handle in our every day work.

The second number on the program, "Activities of Enzymes and Bacteria," by Dr. J. H. Wurdack, was fully as interesting and instructive as the preceding one, although along a widely different line of study. After a short talk covering the subject of enzymes in general, Dr. Wurdack proceeded to explain in detail the cycle which nitrogen follows in passing from one compound to another. He discussed the various nitrogenous compounds of animal excretion and decomposition and their change into ammonia salts; nitrites and nitrates which are used by plants to form the numerous proteids that serve as food for animals and are, through the latter, reverted back to the activities of ammonia,

forming bacteria, thus completing the nitrogen cycle. He also explained quite lucidly the activities of the ammonifying, nitrifying and denitrifying, nitrogen-fixing micro-organisms, ending his talk with an account of the reactions occurring in biological sewage disposal. A full discussion followed the doctor's lecture, and he was asked many questions on the subjects that had been covered, all of which he very satisfactorily responded to.

The lateness of the hour precluded the taking up of the next number on the program. "Discussion of Heroin Sale, Legal and Moral Status."

PHILADELPHIA BRANCH.

The regular monthly meeting of the Philadelphia Branch was held on Tuesday, April 7, at the Drug Club. President E. F. Cook called the meeting to order promptly at 8 p. m. During the short business session which preceded the scientific program of the evening, Mr. J. Rosin was elected to membership in the Branch, and Mr. Theodore Campbell was elected Treasurer for the ensuing year to replace Mr. M. M. Osborne, who was compelled to decline the office because of ill health.

The scientific program was particularly interesting because of the many recent developments and improvements in the use and preparation of biological products and the large attendance of physicians and pharmacists proved that the program was well appreciated.

The following papers were read:

1. Theory Underlying the Use of Serums and Vaccines—By Dr. A. P. Hitchens.
2. A Consideration of Autogenous Vaccines from the Standpoint of Their Preparation and Administration—By Dr. Vincent Lyon.
3. Phylacogens: History, Theory, Preparation, Indications, Dosage and Clinical Results—By Dr. F. C. Waldecker, of New York.
4. Clinical Results from the Use of Curative and Prophylactic Sera and Vaccines—By Dr. J. Hamilton Small.

(The first two papers are printed in this issue.)

The discussion which followed the reading of the papers was participated in by Drs. S. Solis-Cohen, Joseph Head and F. E. Stewart, and also by Messrs. F. M. Apple and W. L. Cliffe.

It was pointed out that the results obtained from the use of bacterial vaccines were not

always encouraging and that stock vaccines as well as autogenous vaccines give variable results under different conditions. In answer to a question propounded by Dr. Apple as to the length of time required for the preparation of autogenous vaccine, Dr. Lyon pointed out that the average length of time would be about seventy-two hours. Dr. Lyon further stated that he believed the preparation of autogenous vaccines would be unprofitable for pharmacists.

The next meeting will be devoted to a consideration of legislative matters.

The executive committee has outlined the following subjects to be discussed during the meetings of the coming year:

"Newer Remedies." (Joint meeting with physicians.)

"Recent Advances in Chemistry."

"Changes in U. S. P. and N. F."

"Commercial Subjects."

"Where May We Expect Modern Pharmacy to Lead?"

"Regulation of Sale of Narcotics and Habit-Forming Drugs and of Poisons."

It is the intention of the committee to arrange with the different Colleges of Pharmacy for lectures on and demonstrations of the new methods and tests of the U. S. P. IX.

ROBERT P. FISCHELIS, Secretary.

NEW ENGLAND BRANCH.

The annual meeting was held on Wednesday evening, April 22d, at the Hotel Plaza in Boston. After the dispatch of routine business, the following officers were elected for the ensuing year:

President—Fred A. Hubbard, Newton, Mass.

Vice President—F. W. Archer, Dorchester, Mass.

Secretary-Treasurer—R. Albro Newton, Southborough, Mass.

Chairman, Committee on Professional Relations—Frank F. Ernst, Jamaica Plain, Mass.

Chairman, Committee on Membership—William H. Glover, Lawrence, Mass.

The gathering was a joint meeting of the Branch and the Boston Association of Retail Druggists.

Dinner was served at 7 o'clock, after which the following speakers were heard: John R. Sawyer, William H. Glover, R. A. Newton, Frank F. Ernst, and Elie H. LaPierre on

"Individual Propaganda," Fred W. Connolly on "Liquor in the Drug Store," and James F. Finneran on "The Attitude of the State Sealer on Apothecaries' Weights and Measures." This latter subject brought out so much discussion that it was nearly midnight when the meeting was adjourned.

R. ALBRO NEWTON, Secretary.

The Pharmacist and the Law

ABSTRACT OF JUDICIAL DECISIONS.

POISONOUS INGREDIENTS—"INJURIOUS TO HEALTH." The flour bleaching case has resulted in a construction by the United States Supreme Court of sub-division fifth or section 7 of the federal Food and Drugs Act, which reads as follows: "That for the purposes of this act an article shall be deemed to be adulterated * * * Fifth, If it contains any added poisonous or other added deleterious ingredient which may render such article injurious to health." Part of the charge of the federal District Court, excepted to by the milling company, read: "The fact that poisonous substances are to be found in the bodies of human beings, in the air, in potable water, and in articles of food, such as ham, bacon, fruits, certain vegetables, and other articles, does not justify the adding of the same or other poisonous substances to articles of food, such as flour, because the statute condemns the adding of poisonous substances. Therefore the court charges you that the government need not prove that this flour, or food-stuffs made by the use of it, would injure the health of any consumer. It is the character—not the quantity—of the added substance, if any, which is to determine this case." On the other hand, the defendant requested the court to charge the jury substantially that the burden was upon the prosecution to prove that by the treatment of the flour by the Alsop Process it had been caused to contain added poisonous or other added deleterious ingredients, to wit, nitrites or nitrite reacting material, which might render the flour injurious to health; and in that connection that the government must prove that any such added ingredients were of such a character and contained in the flour in such quantities, condi-

tions and amounts "as may render said flour injurious to health." This charge was refused by the District Court. The Circuit Court of Appeals reversed the judgment of the District Court for error in its charge and the Supreme Court has now sustained the decree of the Circuit Court of Appeals and remanded the case to the District Court for a new trial.

The Supreme Court said (Justice Day delivering the opinion), that if the testimony introduced on the part of the milling company was believed by the jury, they must necessarily have found that the added ingredient, nitrites of a poisonous character, did not have the effect of making the consumption of the flour by any possibility injurious to the health of the consumer. "The statute upon its face shows that the primary purpose of Congress was to prevent injury to the public health by the sale and transportation in interstate commerce of misbranded and adulterated foods. The Legislature, as against misbranding, intended to make it possible that the consumer should know that an article purchased was what it purported to be; that it might be bought for what it really was, and not upon misrepresentation as to character and quality. As against adulteration, the statute was intended to protect the public health from possible injury by adding to articles of food-consumption, poisonous and deleterious substances which might render such articles injurious to the health of consumers. * * * The instruction of the trial court permitted the statute to be read without the final and qualifying words, concerning the effect of the article upon health [which may render such article injurious to health]. If Congress had so intended, the provision would have stopped with the condemnation of food which contained any added poisonous or other added deleterious ingredient. In other words, the first and familiar consideration is that, if Congress had intended to enact the statute in that form, it would have done so by choice of apt words to express that intent. It did not do so, but only condemned food containing an added poisonous or other added deleterious ingredient, when such addition might render the article of food injurious to the health. Congress has here, in this statute, with its penalties and forfeiture, definitely outlined its inhibition against a particular class of adulteration.

"It is not required that the article of food

containing added poisonous or other added deleterious ingredients must affect the public health, and it is not incumbent upon the government in order to make out a case to establish that fact. The act has placed upon the government the burden of establishing, in order to secure a verdict of condemnation under this statute, that the added poisonous or deleterious substances must be such as may render such articles injurious to health. The word 'may' is here used in its ordinary and usual signification, there being nothing to show the intention of Congress to affix to it any other meaning. It is, says Webster, 'an auxiliary verb,' qualifying the meaning of another verb, by expressing ability, * * * contingency, or liability, or possibility or probability.' In thus describing the offense, Congress doubtless took into consideration that flour may be used in many ways in bread, cakes, gravy, broth, etc. It may be consumed, when prepared as a food, by the strong and the weak, the old and the young, the well and the sick; and it is intended that if any flour, because of any added poisonous or other deleterious ingredient, may possibly injure the health of any of these, it shall come within the ban of the statute. If it cannot by any possibility, when the facts are reasonably considered, injure the health of any consumer, such flour, though having a small addition of poisonous or deleterious ingredients, may not be condemned under the act."

The opinion refers to the view of the English courts construing a similar statute. The English statute provides (§3 of the sale of food and drugs act, 1875): "No person shall mix, color * * * or order or permit any other person to mix, color * * * any article of food with any ingredient or material so as to render the article injurious to health." That section was construed in *Hull v. Horsnell*, 68 J. P., 591, which involved preserved peas, the color of which had been retained by the addition of sulphate of copper, charged to be a poisonous substance injurious to health. There was a conviction in the lower court. Lord Alverstone, in reversing the case on appeal, held that if the conviction proceeded on the ground that the ingredient mixed with the article of food was injurious to health, and not on the ground that the peas, by reason of the addition of sulphate of copper, were rendered injurious to health, the conviction was clearly wrong. All the cir-

cumstances, he said, must be examined to see whether the article of food has been rendered injurious to health.—*United States v. Lexington Mill & Elevator Co.*, 34 Sup. Ct. Rep., 337.

DIAMOND ANTISEPTIC TABLETS—EXCLUSIVE RIGHT TO NAME AND SHAPE OF. On the ninth of February last, Judge John D. McPherson rendered the following judgment:

"It is therefore adjudged, ordered and decreed that the complainant is entitled to the exclusive use of the name "Diamond" as a trade-mark for antiseptic tablets; and that complainant is entitled to the exclusive use of a diamond-shaped figure representation as a trade-mark for antiseptic tablets; and the complainant is entitled to the exclusive right to the conventional shape of a diamond as a shape for its antiseptic tablets. And it is further adjudged and decreed that the use by the defendants of the word "Diamond" or the representation of a diamond-shaped figure or symbol as in any manner indicating or designating antiseptic tablets, was and is a violation of complainant's rights, and, further, that the manufacture and sale of antiseptic tablets made in the conventional shape of a diamond is a violation of complainant's rights.

"And it is further adjudged and decreed that the defendants, their agents, clerks, workmen, servants and attorneys, perpetually refrain and are hereby perpetually enjoined and restrained, from using the name "Diamond" or the conventional figure of a diamond, to designate antiseptic tablets and, further, from manufacturing, selling or otherwise distributing antiseptic tablets made in violation of complainant's rights, diamond-shaped, or in the conventional form of a diamond.

"It is further adjudged and decreed that defendants surrender and deliver up to complainant, to be destroyed, all labels, signs, prints, bottles, packages, wrappers or receptacles in the possession of defendants bearing the said trade marks or either of them, or any colorable imitation thereof, and likewise all antiseptic tablets in their possession made in violation of complainant's rights, in the shape of a diamond."—*Eli Lilly Co. v. Diamond Pharmacal Co.*, *United States Court for the Eastern Dist. of Pennsylvania*.

FOREIGN CORPORATIONS—"DOING BUSINESS"—FILING COPY OF CHARTER—INTERSTATE COMMERCE. A contract with a medical company,

a Minnesota corporation, provided that N. was appointed by the company "as a traveling salesman for its products in the county of M., state of Tennessee," and that the company "agrees to take back all goods left in the possession of the traveling salesman at the time he quits work," and referred to "the expiration of the services of said traveling salesman," etc. A provision on the back of the contract provided that N. was to begin work "as soon as practicable after the goods are received and to work continuously at the agency." During the existence of the agency a note was given by several persons for the agent, to the medical company, for the uncollected price of goods shipped to the agent, namely, \$668.01. One of the makers died and in an action for the settlement of his estate in the courts of the State of Kentucky, where the deceased owned real estate, the medical company made a claim for this sum, which was disallowed. Under the statutes of Tennessee every foreign corporation is required to file a copy of its charter with the Secretary of State, and it is unlawful for it to do or attempt to do any business in the state until it shall have complied with the statute. These statutes have been construed in a number of cases in the Tennessee courts, and it has been uniformly held that, where a corporation does business in that state without complying with the statute, all contracts growing out of such business are illegal and invalid. It was held, on appeal, that the medical company was doing business in Tennessee through its agent, N., who was not a mere purchaser of its products.

The medical company contended that its transactions with N. were interstate commerce, and that therefore the note was binding, although it had not complied with the laws of Tennessee. It was held that this defense was not available, under the facts. These products were not ordered by mail and shipped direct to the company's customers. As a matter of fact, they were shipped to Memphis, and from there distributed to its agent, N., and his brother said that he never ordered any goods except from Memphis. The company's witnesses said that the goods were billed to N. in Minnesota, and were merely sent to Memphis for distribution. Even if there were any doubt as to whether or not the interstate journey ended at Memphis, the interstate journey certainly ended

when the goods were delivered to N. Upon their delivery to him their interstate character ceased; and from that time on, N. as the company's agent, proceeded to sell and deliver the goods in Tennessee. The question of the validity of the note was governed by the law of the place where the transaction was had, as well as the place where it was executed, namely, Tennessee, and not by the law of the place of payment.—*Orr's Adm. v. Orr, Kentucky Court of Appeals*, 163 S. W., 757.

SALE OF DRUGS BY ITINERANT VENDORS—PROHIBITION. The United States Supreme Court holds that a state has power, without violating the equal protection or due process of law clauses of the Fourteenth Amendment to the United States Constitution, to forbid the sale by itinerant vendors of "any drug, nostrum, ointment, or application of any kind, intended for the treatment of disease or injury," although allowing the sale of such articles to other persons. The power which the state government possessed to classify and regulate under consideration (Louisiana Laws, 1894, act No. 49, § 12), is held to be cumulatively sustained and made, if possible, more obviously lawful by the fact that the regulation in question deals with the selling by itinerant vendors or peddlers of drugs or medicinal compounds,—objects plainly within the power of government to regulate.—*Baccus v. Louisiana*, 34 Sup. Ct., 439.

SALE OF INTOXICATING LIQUORS—ATTESTATION OF PERMITS. A druggist, carrying on business in a town in Iowa, in making sales of liquors under permits, omitted to attest two of them, as required by Iowa Code, § 2394. In proceedings for violation of the statute it was held that, although there was no bad faith in the omission, the statute had been violated. An active duty is required of the permit holder in each case, and it must be performed in fact, before he can lawfully make the sale.—*McAllister v. Campbell, Iowa Supreme Court*, 145 N. W., 867.

ACTION FOR PRICE—MISBRANDED DRUGS—AGREEMENT TO ADVERTISE. Action was brought for the purchase price of a quantity of patent medicine called "Nott's Melon Seed Kidney Cure." The defenses were that the plaintiff had broken its contract in regard to advertising agreed therein to be done, and also that the goods were misbranded. The trial court instructed the jury that the only

question which they could consider was whether the drugs in question were misbranded. It was held, on appeal, that this was error, because it appeared that the plaintiff was not able to carry out the advertising part of the contract as it had agreed, and this evidence should have been submitted to the jury. In regard to the alleged misbranding, it appeared that the defendant was prosecuted by the state for having this misbranded article in its store, and that it was fined \$10, and required to pay the costs of the prosecution. It was therefore held that the plaintiff should be required to take back the goods and credit the defendant with the price thereof, in accordance with the terms of the contract of sale.—*Hessig-Ellis Drug Co. v. Harley Drug Co., Nebraska Supreme Court*, 145 S. W., 716.

GASOLINE EXPLOSION—PROXIMATE CAUSE.—An action was brought against the owner of a drug store for injuries to the plaintiff's automobile, caused in the following manner: The plaintiff's son drove the automobile to the defendant's drug store to have it filled with gasoline. After stopping the machine in front of the store and ordering the gasoline, he turned down the light of a lamp, attached to the rear of the automobile about twenty inches under the cap of the tank into which the gasoline was poured, and walked away to talk to some boys. The side of the lamp next to the defendant's store was of metal, so that the light did not show in that direction. The defendant's clerk brought out a five-gallon gasoline can, and, without noticing that the light was burning, placed a funnel in the mouth of the tank, and lifted the can to pour in gasoline, when some of the gasoline ran down, causing an explosion. There was no proof whether the cap on the tank was originally removed by the plaintiff's son or by the defendant's clerk. It was held that the plaintiff's son was negligent in merely lowering the light and removing the tank cap and walking away without explaining to the defendant's clerk that the tank was not ready to be filled. This negligence was a proximate cause of the explosion. Even if the defendant's clerk had been negligent, the plaintiff could not recover, under the rule that where the plaintiff and the defendant are guilty of acts of negligence which together constitute the proximate cause of the injury, then the negligence of the plaintiff, however, slight, bars a recovery.—*Grigsby & Co. v. Bratton, Tennessee Supreme Court*, 163 S. W., 804.

Council Business

COUNCIL LETTER No. 14.

Philadelphia, Pa., April 1, 1914.

To the Members of the Council:

Motion No. 25 (Assignment of Patent Rights to design patent for a Poison Tablet, serial number 801,748, by Norwich Pharmaceutical Company to American Pharmaceutical Association), has received a majority of affirmative votes.

Motion No. 26 (Election of Members). You are requested to vote on the following applications for membership:

No. 55. Frederic Talmage Provost, 1155 Wilson Avenue, Chicago, Ill., rec. by Wm. B. Day and E. N. Gathercoal.

No. 56. Thos. D. Gregg, 1 N. Main St., Harrisburg, Ill., rec. by Wm. B. Day and E. N. Gathercoal.

No. 57. Frederick Fremont Ingram, Jr., 56 10th St., Detroit, Mich., rec. by Caswell A. Mayo and H. M. Whelpley.

No. 58. Alfred Washington Pauley, 3130 N. Girard Avenue, St. Louis, Mo., rec. by H. M. Whelpley and J. A. Wilkerson.

No. 59. George Chalmers Hall, 1422 52d Street, Brooklyn, New York, rec. by J. H. Beal and J. W. England.

No. 60. Reagan Laurence Yeargan, Acme Drug Company, Harriman, Tenn., rec. by E. A. Ruddiman and J. T. McGill.

No. 61. D. Frank Buckley, 688 Salem Street, Malden, Mass., rec. by C. H. Packard and John G. Godding.

No. 62. Burdine H. Carroll, 4734 17th Avenue, North East, Seattle, Wash., rec. by C. W. Johnson and A. W. Linton.

No. 63. F. J. Collinson, Gainesville, Florida, rec. by J. H. Beal and Ernest Berger.

No. 64. Irving Edward Steele, Sergeant, Hospital Corps, U. S. A., Pettit Barracks, Zamboanga, Mind., P. I., rec. by Gabriel Cushman and Arthur Neville.

No. 65. Turner Fee Currens, 57-59 East 11th St., New York, N. Y., rec. by Frank L. McCartney and J. Fred Windolph.

No. 66. Francis Herbert Tapley, 21 Massachusetts Avenue, Boston, Mass., rec. by Anna G. Bagley and John G. Godding.

No. 67. John Francis Correa, Jr., 47 St. Botolph St., Boston, Mass., rec. by Anna G. Bagley and John G. Godding.

No. 68. Charles Garrels, 1110 Fairmont St., Washington, D. C., rec. by H. E. Kalusowski and Henry B. Floyd.

No. 69. Arthur Henry Barnes, Jr., 32 Crown St., Meriden, Conn., rec. by C. H. Packard and Elie H. LaPierre.

No. 70. Maurice Roland Schmidt, Ph.D., 720 W. 181st St., New York City, N. Y., rec. by E. J. Kennedy and Frank L. McCartney.

No. 71. S. Barksdale Penick, 75 Oakland Avenue, Bloomfield, N. J., rec. by William Mansfield and Frank L. McCartney.

No. 72. John Varga, 2017 W. 25th Street, Cleveland, Ohio, rec. by J. H. Beal and J. W. England.

No. 73. Joseph Kepes, 2017 W. 25th Street, Cleveland, Ohio, rec. by J. H. Beal and J. W. England.

No. 74. Bradley Henry Kirschberg, Lorraine Building, Room 10, Schenectady, New York, rec. by J. H. Beal and J. W. England.

No. 75. Mrs. Caroline Wetterstroem, 2844 Colerain Avenue, Cincinnati, Ohio, rec. by Anna G. Bagley and J. H. Beal.

No. 76. Edgar Golden Atkins, Savannah, Tenn., rec. by J. O. Burge and J. H. Beal.

No. 77. Henry Osterman, 122 South Walnut, Seymour, Indiana, rec. by J. H. Beal and Carl E. Loertz.

No. 78. Russell Neely Eberly, 2601 Columbia Avenue, Philadelphia, Pa., rec. by J. W. England and Williard Graham.

No. 79. Frank J. Schmeitzer, Jr., 2567 Bank St., Louisville, Ky., rec. by Addison Dimmett and George Eisele.

No. 80. Bert A. Newhall, 3237 Western Parkway, Louisville, Ky., rec. by Addison Dimmett and George Eisele.

No. 81. Harry A. Stutzlen, 387 Springfield Ave., Newark, N. J., rec. by Frank C. Stutzlen and David Strauss.

No. 82. Hugo Edmund Wiedemann, 1105 Holland Bldg., St. Louis, Mo., rec. by H. M. Whelpley and J. C. Falk.

No. 83. Olva L. Waller, 5610 N. Market St., St. Louis, Mo., rec. by O. J. Cloughley and C. T. Buehler.

No. 84. Charles William Emery, Jr., 1901 Franklin Ave., St. Louis, Mo., rec. by J. W. Mackelden and J. A. Wilkerson.

No. 85. Hampton H. Bentz, 1823 South Jefferson Ave., St. Louis, Mo., rec. by J. W. Mackelden and Jacob Lieberstein.

No. 86. Ernest William Rose, 3032 Olive St., St. Louis, Mo., rec. by J. W. Mackelden and J. A. Wilkerson.

No. 87. Frederick W. Wolff, 6th and Washington Ave., St. Louis, Mo., rec. by J. W. Mackelden and E. H. Wolff.

No. 88. Bernard H. Griesedieck, Sarah and St. Louis Ave., St. Louis, Mo., rec. by J. W. Mackelden and Louis Lieberstein.

No. 89. Elmer G. Gerding, 3400 Chippewa St., St. Louis, Mo., rec. by J. W. Mackelden and C. T. Buehler.

No. 90. Charles Harry Biermann, 5110 Page St., St. Louis, Mo., rec. by H. M. Whelpley and J. W. Mackelden.

J. W. ENGLAND,
Secretary of the Council.

415 N. Thirty-third Street.

COUNCIL LETTER No. 15.

Philadelphia, Pa., April 14, 1914.

To the Members of the Council:

Motion No. 26 (Election of Members; Applications Nos. 55 to 90, inclusive), has received a majority of affirmative votes.

Motion No. 27 (Election of Members). You are requested to vote on the following applications for membership:

No. 91. Roland Treiber Lakey, 271 Belvidere Ave., Detroit, Mich., rec. by Wm. A. Hall and Leonard A. Seltzer.

No. 92. Emil Bruno Kolbe, 671 Junction Ave., Detroit, Mich., rec. by Wm. A. Hall and Leonard A. Seltzer.

No. 93. William H. Allen, Detroit Technical Institute, Detroit, Mich., rec. by Wm. A. Hall and Leonard A. Seltzer.

No. 94. Nathaniel Hugh Jones, 188 Kenilworth, Detroit, Mich., rec. by Wm. A. Hall and Leonard A. Seltzer.

No. 95. Charles S. Elliot, Sgt. 1st Class, Hospital Corps, Reg't Hosp., 23d Infantry, U. S. A., Texas City, Texas, rec. by H. W. Riess and George F. Payne.

No. 96. William J. Remus, 127 LaGrave Ave., Grand Rapids, Mich., rec. by W. C. Kirchgessner and C. H. Packard.

No. 97. Clyde L. Thomas, Grandville, Mich., rec. by W. C. Kirchgessner and C. Herbert Packard.

No. 98. John Perley Regan, Ramblers' Way, North Weymouth, Mass., rec. by Elie H. LaPierre and C. Herbert Packard.

No. 99. George C. Sabin, Grant's Pass, Oregon, rec. by Louis G. Clarke and J. H. Beal.

No. 100. John Werner, Suite 7, Sherbrooke Block, Winnipeg, Canada, rec. by H. E. J. Bletcher and E. Nesbitt.

No. 101. Alexander Campbell, 538 5th Ave., North Saskatoon, Sask., Canada, rec. by H. E. J. Bletcher and E. Nesbitt.

No. 102. Roy L. Connell, Livingston, Mont., rec. by Wm. L. Bomme and F. A. Scheuber.

No. 103. Howard Pinkerton, 81 Grand River Ave., Detroit, Mich., rec. by Wm. A. Hall and Leonard A. Seltzer.

No. 104. George W. Crane, 421 Michigan Ave., Detroit, Mich., rec. by Wm. A. Hall and Leonard A. Seltzer.

No. 105. Andrew Palmerston Young, 153 Grand River Ave., Detroit, Mich., rec. by Wm. A. Hall and Leonard A. Seltzer.

No. 112. Gustav Rehfeld, 4314 Washington Ave., St. Louis, Mo., rec. by Wm. K. Ilhardt and J. A. Wilkerson.

No. 113. Otto Norbert Speckart, 3342 Franklin Ave., St. Louis, Mo., rec. by Sidney Willette and H. M. Whelpley.

No. 114. John Alphonse Sanger, 4101 St. Louis Ave., St. Louis, Mo., rec. by A. C. Schutte and H. M. Whelpley.

No. 115. Daisy Adelaide Frick, Audubon, Iowa, rec. by Zada M. Cooper and Wilber J. Teeters.

No. 116. Earl B. Putt, 641 Washington St., U. S. Food and Drug Lab., New York, N. Y., rec. by J. H. Beal and G. D. Beal.

No. 117. Thos. Jefferson Draper, Brinkley, Ark., rec. by E. A. Ruddiman and J. T. McGill.

No. 118. Fred A. Barker, 134 Main St., Gloucester, Mass., rec. by Theodore J. Bradley and John G. Godding.

No. 119. Frederic Pratt Brooks, 702 Washington St., Norwood, Mass., rec. by C. Herbert Packard and Theodore J. Bradley.

No. 120. George Henry Hartwell, Main and Central Sts., Southbridge, Mass., rec. by C. Herbert Packard and Theodore J. Bradley.

No. 121. Irving H. Robitshek, 86 S. 10th St., Minneapolis, Minn., rec. by E. L. Newcomb and F. J. Wulling.

No. 122. Theo. Bowie, Grady Hospital, Atlanta, Ga., rec. by George F. Payne and Mrs. M. M. Gray.

No. 123. Richard Calvin Stofer, 28 Hayes St., Norwich, N. Y., rec. by G. M. Beringer and Franklin M. Apple.

J. W. ENGLAND,
Secretary of the Council.

415 N. Thirty-third Street.

COUNCIL LETTER No. 16

Philadelphia, Pa., April 6, 1914.

To the Members of the Council:

The following letter from James H. Beal, under date of April 15, 1914, has been received by J. W. England, Chairman of Committee on Publication, but in view of the peculiar urgency of the situation and the fact that if the Committee on Publication elected an Acting Editor, such action would have to be approved by the Council, and the further fact that the selection of an Acting General Secretary has to be made by the Council itself, it is thought best to bring the whole subject directly before the Council for action:

"I desire to be relieved of my position as Editor and General Secretary at as early a date as convenient, say May 1st, or after the issue of the JOURNAL for that month. My reasons for this you, of course, already know.

During the past winter the attacks from my old enemy have been coming with increasing frequency and severity. A few days of unusual mental or physical stress are sufficient to bring on quite annoying and some rather alarming symptoms.

After careful consideration, and consultation with my medical adviser, I am convinced that the only thing I can do is to free myself entirely from the constant strain and responsibility which are inseparably attached to the position which I hold. By being relieved early this spring, I can live out of doors during the summer, and take such exercise as will enable me to put myself in shape for another winter; but I never expect to be in condition to again take up any work which will confine me to an inflexible schedule of duties.

Your kindness of heart will probably prompt you to suggest that I take a vacation and look forward to resumption of the editorship at some future date, but such an arrangement would not be at all satisfactory, as I could not divest myself of a sense of responsibility, which is the thing above all that I wish to do.

I suggest that the Committee on Publication select Ernest C. Marshall as Acting Editor and Acting General Secretary until the Detroit meeting, which will give plenty of time to settle upon some one for the permanent position. I will keep in close touch with Mr. Marshall, and once relieved of the feeling of responsibility for the JOURNAL, will be able to give him all necessary advice and instructions without worry to myself.

As it would hardly be proper to allow him my salary in addition to his own, would suggest that the Committee pay him for *all of his duties* at the rate of \$3,000.00 per year from the time when he takes full charge to the first of September. This would be at the same rate as was allowed me for the same work prior to the Nashville meeting.

If the Committee will take *immediate action*, the matter should be in shape so that I can retire from the work officially not later than the middle of May, or, at the outside, the first of June."

Motion No. 28 (Acceptance of Resignation of James H. Beal as Editor and General Secretary). Do you accept the resignation of James H. Beal as Editor and General Secretary to take effect May 1, 1914, or after the issue of the JOURNAL for that month?

Motion No. 29 (Election of Ernest C. Marshall as Acting Editor and Acting General Secretary). Are you in favor of electing Ernest C. Marshall, at present Advertising Manager of the JOURNAL, as Acting Editor of the JOURNAL and Acting General Secretary of the Association until the annual meeting of the Association at Detroit during the week of August 24 next, the Association to pay him for all of his duties at the rate of three thousand dollars per year from the time when he takes full charge to the first of September?

J. W. ENGLAND,
Secretary of the Council.

415 N. Thirty-third Street.

UNITED STATES PUBLIC HEALTH SERVICE.

List of Changes of Stations and Duties of Commissioned and Other Officers of the United States Public Health Service for the Period Ending April 15, 1914.

Cofer, L. E., Assistant Surgeon General. Directed to proceed to Boston, Mass., for conference with the medical officer in charge of the Marine Hospital relative to ration issued to patients and attendants. March 20, 1914.

Carter, Henry R., Senior Surgeon. Directed to make necessary trips between Baltimore, Md., and Washington, D. C., for the purpose of giving lectures on malaria and yellow fever to student officers now taking course of instruction at the Hygienic Laboratory. March 21, 1914.

Woodward, R. M., Surgeon. Granted leave of absence for two months from February 3, 1914. March 19, 1914.

Wertenbaker, C. P., Surgeon. Granted four days' leave of absence, on account of sickness, from March 20, 1914. March 24, 1914.

Eager, J. M., Surgeon. Authorized to attend meeting of Permanent Committee of the International Office of Hygiene at Paris, France, beginning April 21, 1914. March 20, 1914.

Nydegger, J. A., Surgeon. Directed to proceed to the Immigration Station, Ellis Island, N. Y., for the purpose of witnessing the various tests there used for the determination of mental development. March 20, 1914.

Lumsden, L. L., Surgeon. Directed to proceed to certain counties in West Virginia and Indiana for investigations of typhoid fever with special reference to rural sanitation. March 18, 1914.

Corput, G. M., Surgeon. Directed to proceed to New Orleans, La., on business connected with procuring supplies for the station when occasion demands, during the period April 1, to June 30, 1914. March 21, 1914.

Goldberger, Jos., Surgeon. Directed to proceed to Richmond, and other points in the state of Virginia, to visit insane and other institutions for the purpose of inquiring into the prevalence and origin of pellagra. March 19, 1914.

Simpson, Friench, Passed Assistant Surgeon. Relieved from duty at San Francisco, Cal., and special duty at Seattle, Wash., and directed to proceed to Washington, D. C., and report to Director, Hygienic Laboratory, for duty in investigation of occupational diseases. March 18, 1914.

Olesen, Robert, Passed Assistant Surgeon. Upon completion of present assignment to the Hygienic Laboratory for instruction, directed to report to the Director for duty. March 18, 1914.

Lanza, A. J., Passed Assistant Surgeon. Upon completion of present assignment to the Hygienic Laboratory, for instruction, relieved from duty at the Fort Stanton Sanatorium and directed to report to the Director for duty. March 18, 1914.

Directed to undertake investigations of the influence of migration of tuberculosis persons in interstate traffic in the states of Arizona and Colorado. March 18, 1914.

Grimm, R. M., Passed Assistant Surgeon. Relieved from duty at the Marine Hospital, Savannah, Ga., and directed to report to the Director, Hygienic Laboratory, for duty. March 18, 1914.

Parcher, George, Assistant Surgeon. Directed to report to the commanding officer of the U. S. Revenue Cutter Miami at Tompkinsville, N. Y., for duty in the ice patrol of the North Atlantic Ocean. March 18, 1914.

Glanville, W. E., Assistant Surgeon. Upon completion of present assignment to the Hygienic Laboratory for instruction, directed to report to the Director for duty. March 18, 1914.

Baughman, D. S., Assistant Surgeon. Relieved from duty at the Marine Hospital, Chicago, Ill., and directed to proceed to Seattle,

Wash., and report to Surgeon B. J. Lloyd for duty. March 18, 1914.

Hoskins, J. K., Sanitary Engineer. Directed to proceed to Harrisburg, Pa., for consultation with state health authorities in regard to securing sanitary data for use in investigations of pollution of the Ohio river. March 18, 1914.

Shoub, H. L., Sanitary Bacteriologist. Directed to proceed to Washington, D. C., and report to the Director of the Hygienic Laboratory for duty in connection with field investigations of stream pollution. March 18, 1914.

Sharpe, W. K., Jr., Epidemiologist. Granted two days' leave of absence en route to Washington, D. C. March 21, 1914.

Stoner, G. W., Senior Surgeon. Granted five days' leave of absence from March 21, 1914, under paragraph 193, Service Regulations. March 26, 1914.

Wertenbaker, C. P., Surgeon. Relieved from duty at Norfolk, Va., and directed to proceed to Providence, R. I., not later than May 1, 1914, and assume charge of the Service at that port. March 24, 1914.

Grubbs, S. B., Surgeon. Relieved from duty at Providence, R. I., upon arrival of Surgeon C. P. Wertenbaker, and directed to proceed to Louisville, Ky., and assume charge of the Service at that port. March 24, 1914.

Lumsden, L. L., Surgeon. Referring to Bureau orders of March 18, 1914, directed while conducting investigations of rural sanitation in West Virginia to return to Washington, D. C., at intervals of at least two weeks for conference and to make bacteriological examinations of specimens collected. March 28, 1914.

Goldberger, Joseph, Surgeon. Directed, in connection with investigations of pellagra, to proceed at such times as may be necessary to Catlett, and other places in the State of Virginia, to make epidemiological studies of cases of the disease. March 27, 1914.

McLaughlin, A. J., Surgeon. Granted six months' leave of absence from April 1, 1914, without pay. March 27, 1914.

Pierce, C. C., Surgeon. Upon completion of the course of instruction at the Hygienic Laboratory, directed to report to the Bureau for duty in connection with the preparation of a Service exhibit for the Panama-Pacific Exposition. March 25, 1914.

Frost, W. H., Passed Assistant Surgeon. Authorized, in conjunction with Sanitary Chemist H. W. Streeter, to present before the section on water, sewage and sanitation of the American Chemical Society an outline of the work being carried on in the investigation of the pollution of the Ohio River and the Laboratory work in connection therewith. March 25, 1914.

Paine, Liston, Assistant Surgeon. Relieved from duty at the Marine Hospital, Boston, Mass., and directed to proceed to Cincinnati, Ohio, and report to Passed Assistant Surgeon W. H. Frost for duty in the investigations of the pollution of the Ohio River. March 26, 1914.

Ruoff, John S., Assistant Surgeon. Granted one month and seven days' leave of absence, on account of sickness, from February 24, 1914.

Stiles, C. W., Professor of Zoology. Detailed at the request of the Eighth District Medical Society of North Carolina, to attend the annual meeting of that society, to be held at Greensboro, N. C., April 2-3, 1914, and present an address on a public health subject of general interest. March 24, 1914.

Phelps, E. B., Professor of Chemistry. Detailed to attend the meeting of the American Chemical Society, to be held at Cincinnati, Ohio, April 7-10, 1914, for the purpose of presenting a paper on chemical studies of the pollution of the Ohio River. March 31, 1914.

Seidell, Atherton, Technical Assistant. Detailed to attend the meeting of the American Chemical Society to be held at Cincinnati, Ohio, April 7-10, 1914, for the purpose of presenting a paper before the pharmaceutical section of the society. March 31, 1914.

BOARD CONVENED.

Board of commissioned medical officers convened to meet at the Bureau, Monday, April 27, 1914, at 10 o'clock a. m., for the physical and mental examination of candidates to determine their fitness for appointment as Assistant Surgeons in this Service. Detail for the board: Assistant Surgeon-General W. G. Stimpson, chairman; Assistant Surgeon-General W. C. Rucker, member; Passed Assistant Surgeon Hugh de Valin, recorder. March 27, 1914.

Williams, L. L., Surgeon. Granted one day's leave of absence, on account of sickness, March 26, 1914. April 4, 1914.

Guiteras, G. M., Surgeon. Granted three days' leave of absence, on account of sickness, March 22, 1914. April 4, 1914.

Brown, B. W., Surgeon. Granted one month's leave of absence to date from arrival in San Francisco, Cal. April 3, 1914.

Clark, T., Surgeon. Directed to proceed to the states of West Virginia and Virginia for the purpose of completing investigations of the prevalence of trachoma and other infectious diseases among the mining and mountainous population of those states. April 3, 1914.

Directed to proceed to Huntington, W. Va., for the purpose of addressing the public health meeting to be held in that city, April 3, 1914. April 6, 1914.

Anderson, John F., Surgeon. Directed to proceed to Toronto, Can., for the purpose of attending the annual meeting of the American Association of Pathologists and Bacteriologists to be held in that city April 9-11, 1914. Also returning, to stop in New York, N. Y., for the purpose of attending the annual meeting of the Commission of Milk Standards, April 13, 1914. April 2, 1914.

Schereschewsky, J. W., Surgeon. On request of the Joint Board of Sanitary Control of the Garment Trade and the Commissioner of Health of New York, directed to proceed to New York, N. Y., and conduct, in co-operation with the above agencies, an investigation into the sanitary condition of the garment workers' trade and the physical status of employees engaged therein. April 7, 1914.

Warren, B. S., Surgeon. On request of the State Board of Health of Louisiana, directed to proceed to New Orleans in time to attend a conference upon April 20, 1914, of local and state health officers, mayors, and other authorities relative to public health work, with particular reference to the sanitary inspection and regulation of public buildings and places of public assembly. April 2, 1914.

Creel, R. H., Passed Assistant Surgeon. Directed to proceed immediately to Havana, Cuba, on account of plague infection at that port. April 6, 1914.

Collins, G. L., Passed Assistant Surgeon. Granted two days' leave of absence, on account of sickness, March 28 and March 30, 1914. April 3, 1914.

Spratt, R. D., Passed Assistant Surgeon. Upon the request of the Secretary of Labor, directed to proceed, at the first convenient opportunity, to Wheeling, W. Va., for the purpose of making a re-examination of aliens Sada and Barbara Nassif. April 2, 1914.

Frost, W. H., Passed Assistant Surgeon. Granted two days' leave of absence, March 29-30, 1914, under paragraph 193, Service Regulations. April 2, 1914.

Simpson, Friench, Passed Assistant Surgeon. Directed to proceed to New York, N. Y., for duty under Surgeon J. W. Schereschewsky, in connection with investigations of the sanitary conditions of garment workers' trades and the physical status of employees engaged therein. April 7, 1914.

Bryan, W. M., Passed Assistant Surgeon. Relieved from duty at the Marine Hospital at Stapleton, N. Y., and directed to proceed to Washington, D. C., and report to the Director of the Hygienic Laboratory for duty; then to proceed to Martinsburg, W. Va., and report to Surgeon L. L. Lumsden for duty in field investigations of typhoid fever. April 6, 1914.

Olesen, Robert, Passed Assistant Surgeon. Directed to proceed to New York, N. Y., for duty under Surgeon J. W. Schereschewsky, in connection with investigations of the sani-

tary conditions of garment workers' trades and the physical status of employes engaged therein. April 7, 1914.

Lanza, A. J., Passed Assistant Surgeon. Directed, upon request of the Secretary of the Interior, in connection with Bureau order of March 18, 1914, to make sanitary investigations of metal mines at Butte, Mont., and Cripple Creek, Col., and vicinity, also of the mining industry in Arizona with special reference to "Miners' asthma." April 3, 1914.

In carrying out above order, directed to proceed by way of Franklin Furnace, N. J., for the purpose of inspecting the sanitation of the mines located there, and Pittsburgh, Pa., to become familiar with the operations of the laboratory maintained by the Bureau of Mines. April 7, 1914.

Ridlon, J. R., Passed Assistant Surgeon. Directed in connection with the investigations of pellagra to assume charge of the Marine Hospital at Savannah, Ga. April 6, 1914.

Watkins, J. A., Assistant Surgeon. Relieved from duty in the Hygienic Laboratory, and on request of the Secretary of the Interior, directed to proceed to Pittsburgh, Pa., for the purpose of making investigations of the sanitary conditions of metallurgical plants in the Pittsburgh district, as they affect the health of employes. April 3, 1914.

Knox, H. A., Assistant Surgeon. Granted 11 days' leave of absence on account of sickness, from March 17, 1914. April 4, 1914.

Glanville, W. E., Assistant Surgeon. Relieved from duty at the Hygienic Laboratory, and directed to proceed to San Francisco, California, and report to the Medical Officer in charge of the quarantine station for duty, and assignment to quarters. April 6, 1914.

Thometz, H. M., Assistant Surgeon. Directed to proceed to Seattle, Washington, about April 20, 1914, and report to the commanding officer of the Revenue-Cutter "Tahoma" for duty during the summer cruise in Alaskan waters. April 6, 1914.

Treadway, W. L., Assistant Surgeon. Granted 15 days' leave of absence from April 4, 1914. April 4, 1914.

Stiles, C. W., Professor of Zoology. Detailed to attend the meeting of the South Carolina Medical Association at Florence, S. C., April 15-16, 1914. April 3, 1914.

Voegtlin, Carl, Professor of Pharmacology. Directed to proceed to Catlett, Va., for the purpose of collecting material and securing data for use in connection with investigations of pellagra. April 3, 1914.

Wells, W. F., Sanitary Chemist. Directed to proceed to Cumberland, Md., and vicinity for the purpose of making chemical and bacteriological analyses of samples of water in connection with investigations of the pollution of the Potomac River. April 4, 1914.

Kerr, J. W., Assistant Surgeon-General. Directed to proceed, by way of Providence, R. I., to Boston, Mass., for consultation with the state authorities regarding methods of sanitary administration. April 9, 1914.

Rucker, W. C., Assistant Surgeon-General. Directed to proceed to Baltimore, Md., on April 14, 1914, for the purpose of delivering a stereopticon lecture on the subject of "Bubonic Plague." April 10, 1914.

Clark, T., Surgeon. Detailed to attend the meeting of the Virginia Public Health Association, to be held at Charlottesville, Va., April 23, 1914, for the purpose of presenting a paper on trachoma. April 13, 1914.

von Ezdorf, R. H., Surgeon. Detailed to attend the meeting of the section on Malaria Eradication of the National Drainage Congress in Savannah, Ga., April 22-25, 1914, for the purpose of presenting a paper describing present and contemplated governmental activities in relation to malaria investigations. April 13, 1914.

Fox, Carroll, Surgeon. Granted one day's leave of absence April 14, 1914. April 11, 1914.

Pierce, C. C., Surgeon. Directed to proceed to New York, N. Y., for the purpose of investigating a closet-closing device now operating on certain railroads; also while in New York to visit such places as may be necessary, to collect information which may be of assistance in the preparation of the Service exhibit at the Panama-Pacific International Exposition. April 11, 1914.

Glanville, W. E., Assistant Surgeon. Directed to report, April 20, 1914, to the commanding officer of the Revenue-Cutter "Bear" at San Francisco, Cal., for duty during the summer cruise in Alaskan waters. April 10, 1914.

Jenkins, Luther W., Assistant Surgeon. Directed to report, April 15, 1914, to the commanding officer of the Revenue-Cutter "Manning" at San Francisco, Cal., for duty during the summer cruise in Alaskan waters. April 7, 1914.

Derivaux, R. C., Assistant Surgeon. Directed to proceed, when directed by Surgeon R. H. Von Ezdorf, to points in the South, particularly in the States of Arkansas, Mississippi, South Carolina and Tennessee for the investigation of the prevalence of malaria and the collection of pathological material and specimens of mosquitoes. April 13, 1914.

Treadway, W. L., Assistant Surgeon. Granted two days' additional leave of absence from April 19, 1914. April 14, 1914.

Crane, J. F., Acting Assistant Surgeon. Granted seven days' leave of absence from April 10, 1914. April 10, 1914.

Marsh, W. H., Acting Assistant Surgeon. Granted four days' leave of absence from April 27, 1914. April 11, 1914.

Smith, E. E., Sanitary Bacteriologist. Directed, when instructed by the medical officer in charge of the investigations of the pollution of the Ohio River, to proceed to such points on the Ohio River watershed, as he may designate, for the purpose of collecting samples, of water, making sanitary surveys, and laboratory investigations. April 9, 1914.

Veldee, Milton V., Sanitary Bacteriologist. Directed, when instructed by the medical officer in charge of the investigations of the pollution of the Ohio River, to proceed to such points on the Ohio River watershed as he may designate, for the purpose of collecting samples of water, making sanitary surveys, and laboratory investigations. April 9, 1914.

Official:

RUPERT BLUE,
Surgeon-General.

Changes of Address

All changes of address of members should be sent to the General Secretary promptly.

The Association will not be responsible for non-delivery of the Annual Volume or Year Book, or of the JOURNAL unless notice of change of address is received before shipment or mailing.

Both the old and the new address should be given, thus:

HENRY MILTON,

From 2342 Albion Place, St. Louis, Mo.
To 278 Dartmouth St., Boston, Mass.

Titles or degrees to be used in publications or in the official records should be given, and names should be *plainly* written, or type-written.

cago, Ill.

THE PRICE CUTTER.

A great obstacle to honest constructive effort is the *Price Cutter*. Next in line comes the blackguard who *encourages* the price-cutting and endeavors to force all competitive effort down to the dead level of mediocrity.

We met one of his ilk the other day. "What," says he, "you charge \$2.50 for that job when Faket charges only a dollar! You're a robber!" Yes, Faket does do it for a dollar and it may be as well done as my \$2.50 job. The difference is that Faket is a *one dollar man* while I'm a \$2.50 man. In this free country there is nothing to keep that blackguard from going to Faket, but in trying to bulldoze me down to Faket's level he violates all decency. I have the indisputable right to place my own value upon my own time and services. Why will one perform a laparotomy for \$50 while another asks \$500? It is generally a matter of individual attainment. The \$50 man has only a \$50 reputaion at stake, while the \$500 man assumes \$500 worth of responsibility. The \$450 difference can often be accounted for in the cheap man's lack of experience; lack of professional standing and pride; financial stress, or lack of moral stamina to ask an honest price for an honest job.

It is an odd commentary upon human nature that the man who hammers down the price is the first to raise a howl when his own toes are trod upon. He exacts the last farthing, but *you* must always make concessions. Keen competition has fixed a fairly stable price on all forms of human endeavor, as well as on commodities. These prevailing prices take into account a great many economic factors.

In the case of merchandise there must be added to the actual cost of the article, the merchant's overhead expense, which includes rent, salaries, investment, insurance, losses in deterioration and bad accounts, telephone, lighting, freight, advertising, etc., etc. If an article costs the dealer seventy-five cents, he does not "break even" until he has added on twenty-five percent or more of operating cost. This accounts for the difference in the price listed by producers and the *cost* price charged by the dealer.

As a rule staple articles allow a margin just sufficient to cover this "overhead" expense and a small excess as profit. Therefore, the man who "cuts" on such staple articles is bound to be an impostor, for the reason that he is compelled to make the difference good on merchandise, the value of which is unknown to the purchaser.

In the case of skilled labor or professional services, the factors of individual attainment and the law of supply and demand apply. A student out of college will give his services for a fraction of what he will demand later in his experience. He has no moral right to exact a *fancy price* for his services. The apprentice is not entitled to the same emolument as the master workman, although he may perform a given piece of work quite as creditably.

The Price Cutter will continue to have his following, but competition and achievement are entitled to other considerations than arbitrary calculation of dollars and cents. It is some consolation to those who have been imposed upon to know that the "cut-throat" must eventually come to grief.—*California State Journal of Medicine*.

The Journal of the American Pharmaceutical Association

Volume III

JUNE, 1914

No. 6

Office of Publication, 79-89 North Third St., Columbus, Ohio.

Subscription, \$4.00 per annum, within the United States. To Canada, \$4.35. To other foreign countries in Postal Union, \$4.50 per annum.

Entered at the Postoffice at Columbus, Ohio, as Second-Class matter.

DR. BEAL'S RESIGNATION.

THE members of the Association, without exception, will most gladly receive the news that the resignation of Dr. Beal, as Editor of the Journal and General Secretary of the Association, has not been accepted by the Council to take immediate effect, but that action upon that matter has been practically deferred until the convention in August, at which time every friend of the A. Ph. A., and of American pharmacy, will hopefully wish that Dr. Beal's health will have been so restored that he may be able again to resume the position which he has so signally honored.

In making this statement, I beg to be pardoned for intruding a personal acknowledgment of my most heartfelt regard and esteem for my chief, Dr. Beal, and to express my most sincere thanks to him, for the kindness and courtesy with which he received me as his assistant, and to say, that nothing could give me more satisfaction than to see him fully restored to health and once more occupying the desk and place he has made for himself.

In my occupancy of the position of Acting Secretary of the Association and Acting Editor of the Journal, I earnestly solicit from the members their sympathetic consideration. That I cannot fully fill the place of Dr. Beal, it is unnecessary for me to avow, but to him who has reposed this confidence in my ability, in selecting me as the temporary occupant of his place, and to every member of the Association, from the highest to the lowest, I pledge my most earnest effort to warrant his and their confidence and esteem. Should I fail in this endeavor it will not be from lack of desire to serve the Association to the utmost extent of my humble ability, to which effort I pledge my whole heart and soul.

ERNEST C. MARSHALL,
Acting Editor and Acting General Secretary.

ASSOCIATION MEETINGS.

DURING the months of June and July many meetings of State Associations occur, and the pharmacists of the country will gather together in state conventions to consult and to deliberate as to the manner by which the interests of the profession,—and consequently their own most important interests,—can be advanced.

At these annual gatherings “many men of many minds” will convene and it is greatly to be desired that from their deliberations will come great and lasting good to the whole profession.

The members of our craft,—more than those of any other,—need the broadening influence which comes from association-work; the touching of elbows with other men of their profession; from the exchange of views with their fellows; from the tolerant listening to, and the weighing of other men’s opinions.

It is not the relinquishment of our own ideas to respectfully hear and to carefully weigh the arguments which another brain has wrought out. In this great land of ours, where education is so universally diffused, the man from the back-country, in a small store, has perhaps used his gray matter to good advantage and, from his thought, may have evolved ideas productive of much good, if adopted. Nothing advances the interests of any organization more than toleration of other’s opinions, and a desire to profit by the best thoughts of every one of its members, and we should, in all of these conventions, patiently listen to, and sift these thoughts carefully, in order that no wheat be thrown away with chaff,—nothing wasted that should be preserved.

The officers of all these associations have earnestly worked to promote the interests of the Association and the profession during the past year. They have kept a vigilant eye upon all legislation and have guarded against unwise attempts to fetter and to curb the general and natural advancement of the trade. To them should be accorded an unqualified support and an earnest loyalty. They have not worked for self-aggrandizement, but for the good of all. Let us then go to our State Conventions with an earnest purpose to support loyally all the efforts these officers have made in the interests of our craft. Let us listen thoughtfully and weigh well, all that is said at these meetings upon every question which is presented, and let us dedicate this period to the uplift and the advancement of the profession to which we look for our welfare and support. Not alone to play and to pleasure should these gatherings be devoted, but our Association meetings should mean work for every one, and let us from this work derive an enthusiasm, a loyalty, not alone to our state organizations, but to the great national organizations which make the profession of pharmacy a power in the nation. From this inspiration maybe will come a desire to go to Detroit to participate in the great national convention of the American Pharmaceutical Association from whose annual gatherings no one ever returned without being a better, a broader and a wiser man. What glorious results might follow if every pharmacist in the country came to the Detroit meeting and aligned himself and his influence in support of the policies, the achievements and the traditions of the A. Ph. A., and, returning home, would labor earnestly in his field of influence to advance the true interests of pharmacy, along the broad lines laid down by

Squibb, Maisch, Procter and the many others who labored so long and earnestly to make pharmacy a true and an honored profession,—one ranking with any other in the world. It is not necessary that members should devote their valuable time to work for the Association; to sacrifice anything. It only calls for them to hold it in their heart of hearts as *the* Association of the country and the world, the one which has ever held its rudder true to the highest ideals of pharmacy; to look up to it as their *Alma Mater*,—their loving mother,—whose ever-watchful care is over and around them, ever seeking for their weal.

In this spirit the old-time men of our craft served their guild, and made it their protection against the tyranny of the over-lords and others who would oppress them. To-day the Pharmaceutical Guild of the Nation,—the American Pharmaceutical Association,—has taken the place of the guild of the old burghs, for, under modern conditions, the men of Boston know the men of San Francisco as well as the men of olden time knew their *confreres* of the next city, and this intimate connection should make for a solidarity, a harmony and a strength which should be irresistible for good if properly utilized and fostered and it is by association-work that such results may be achieved.

If every member would grapple this thought to his soul and take this interest in the Association, much good would result to American pharmacy and every one of its members would attain to a higher, better and a more profitable position in the community.

DETROIT,—THE BEAUTIFUL.

Anyone who has visited Detroit can readily answer the question—"Why is Detroit the greatest convention city in the world?" Space precludes our giving the thousand and one reasons here. Suffice it to say that Detroit fully lives up to the reputation expressed in its world-wide known slogan,

"In Detroit Life's Worth Living Every Day!"

By virtue of its location, Detroit is preëminently the Convention City of America. Situated on the high terraced bank of its beautiful river,—the noble strait which connects Lake St. Clair and Lake Erie,—its climate is ideal for mid-summer gatherings. Its many beautiful public buildings, churches and other edifices delight the artistic eye, while a lover of Nature finds keen pleasure in the enjoyment of its magnificent parks, its boulevards and suburban drives.

Detroit will be the Mecca for many conventions this coming summer. The greatest of these will be that of the American Pharmaceutical Association which will be held August 24-29. An efficient entertainment committee has arranged a splendid program for your pleasure and benefit,—they say “There never was a better one.” For this week Detroit will be the drug-center of the world where the great men of the profession will gather and confer as to the welfare of our noble craft. Your presence will add to the success of the convention, and you will have “the time of your life.”

Send your notice at once to the Local Secretary, Mr. Leonard A. Seltzer,—tell him you will be in Detroit with us, and “be a Booster”; get your fellow-pharmacists to come along, and with them get away from the daily grind and broaden your horizon. You can greatly serve your Committee on Accommodations by sending your notice to-day. And you will also be assured of better quarters and service. You are confidently expected and will be cordially welcomed by your brothers of Detroit. Omar Khayyam sings:

“When all the temple is prepared within,
Why waits the drowsy worshipper without?”

Why then wait? Say to yourself, “I’ll be in Detroit in August,” and **BE THERE.**

THE DETROIT HOTELS.

Members of the American Pharmaceutical Association, expecting to attend the Detroit meeting, beginning Monday, August 24, will be interested to know about the various hotels and their rates. May we suggest, too, that reservations be made reasonably early in order to avoid any doubt about getting satisfactory accommodations? Detroit is well filled with tourists in July and August, and it would be most unwise not to reserve your rooms and thus make sure of getting them.

The hotels are as follows:

Pontchartrain (official headquarters)—\$2 to \$2.50 for single room, \$3 to \$4 for double room; \$3, \$3.50, \$4, \$5 for single room with bath; \$5, \$6, \$8 for double room with bath.

Cadillac (one block away)—\$2 to \$5; rooms with bath 50 cents extra; \$1 less than twice the price when two occupy a room.

Griswold (two blocks away)—\$1.50, \$2, \$2.50, \$3; \$2 and upward for rooms with bath; add \$1 to the price when two occupy a room.

Ste. Claire (American plan—two blocks away)—\$2.50 to \$4.50; \$3.50, \$4 and \$4.50 with bath.

Tuller (four blocks away)—\$1.50 and upwards; add \$1.50 when two occupy a room.

Charlevoix (five blocks away)—\$1.50 and upwards; add \$1 to price when two occupy a room.

Wayne (eight blocks away)—\$2, \$2.50, \$3, \$3.50, \$4; \$3.50 and upwards for rooms with bath; \$1 additional when two occupy a room.

Plaza (five blocks away)—\$2 for single rooms; \$3 for double rooms; meals 50 cents each.

Lenox (five blocks away)—\$1 single room; \$1.50 double room; \$9 per week single room with bath; \$12 per week double room with bath.

Addison (eight blocks away)—\$2 and \$2.50 for one room; \$3 and \$3.50 for two rooms; \$4 and \$5 for three rooms.

It will be observed that the only American hotel in the list is the Ste. Claire.

EXCURSION FROM DETROIT TO PT. COCKBURN AND RETURN.

The trip from Detroit to Toronto is made in the elegantly appointed trains of the C. P. R. Leaving Fort St. Union Depot, the train soon passes upon the railway ferry, to be transferred to Windsor in Canada. From the middle of the stream, an excellent view of Detroit may be observed. Leaving Windsor, the train passes through a rich farming country to Chatham, London, Woodstock, Galt, Milton and Erindale, all prosperous manufacturing and farming communities. At Cooksville, Dixie, Summerville and Islington many Toronto people have their summer homes. At West Toronto, those tourists who do not care to visit Toronto, can make connection for Bala. Toronto is, however, most inter-

Shooting the Rapids — Muskoka Lakes.

esting, and well repays a visit to Canada's "Queen City." From Toronto to Bala are many beautiful views, among them being the Falls of the Severn and Muskoka. Leaving Bala, the tourist passes through the beautiful lakes of Muskoka, Rosseau and Joseph, which are situated some hundred and twenty miles from Toronto, and on the east of the Canadian Pacific line. Stretching fifty miles further north, is the famous Georgian Bay country. These two districts, comprising as they do rivers, lakes, islands and bays innumerable, form one of the greatest vacation lands yet discovered. This romantic network, of open lakes and intricate waterways, every year rings with the laughter of the city dweller, who finds in the clear waters and pine-clad islands of the Muskokas, in the sheltered inlets of Georgian Bay and Point Au Baril, and on the rocky shores of the French River that outdoor life which fills the lungs with purest of ozone, the body with new vigor, and the heart with new happiness.

"Own your own island," say some, and surely there is a wide choice, for there are thirty thousand islands in Georgian Bay. Those of more moderate desires

Canoe Sailing on Georgian Bay.

can, for a dollar a day, in some lake hotel or boarding house, breathe in the balsamic odors of pine and spruce, and with the daily swim, happy picnics and canoe parties, find exquisite enjoyment and regain health and joy of life.

Then there are those who scorn dwellings, and prefer camp-life in the open, taking with them bacon, flour, butter, sugar, salt and tea, needing but a fish or two from the cool waters to complete all that an epicure could crave.

By Canadian Pacific train from Toronto to Bala, the gateway of the Muskoka district, is some four hours' ride through a rich agricultural section, and a good service,

combined with the fact that there are both United States and Canadian customs officers located at Bala station, makes the rail-journey unusually free from care and trouble. At Bala, transfer is made from train to steamer, and close connections insure quick arrival at any point on the lakes.

The principal lakes are three in number, Muskoka being the largest, Joseph next in size, and Lake Rosseau the smallest. They contain between four and five hundred islands, ranging from one of over 1999 acres, to those containing but a single tree or a rugged mass of rock. The majority, however, are densely crowded with pine, balsam, cedar, birch, maple, oak and other varieties of tree life.

These attractive lakes, however, do not monopolize the attention of the vacation seeker, for there are many rivers in this lovely region which offer an almost endless variety of canoe and motor-boating trips. Lake Muskoka itself is twenty-one miles long, and being joined with the other lakes by channels, a month could be easily spent in exploring their inlets, bays and rivers. Water sports are very popular in the Muskoka

Camping on Georgian Bay.

Regatta — Lake Rosseau — Muskoka Lakes.

Lakes, regattas being a weekly occurrence, and often parties located at one end of the lakes will boat to a neighboring regatta, and enjoy the sport always to be found at these gatherings. At the many hotels and boarding-houses on the lakes will be found good tennis courts, bowling greens and golf links, where these pastimes may be enjoyed.

In the Georgian Bay District, where everybody lives on islands, yachting is one of the great attractions, and canoeing is safely enjoyed among the many passages. There is splendid fishing among the islands, bass being very plentiful. Parry Sound is a favorite point, but a little further north, at Point Au Baril, will be found a vacation-land which all will depart from with regret and a longing to return.

Its natural attractions are very wonderful, in fact the hundreds of islands appear to have been designed to supply the need of salubrious resorts, where, in the summer, people might go and forget business cares and be happy in a land of

Victorious Crew in War Canoe Race — Muskoka Lakes.

enchantment. The fishing is exceptionally good, black bass, pickerel, pike and muskalonge being found in abundance. In this region and the French and Pickerel River Districts, those who prefer camping-out, to hotel life, will find splendid facilities, as there are people who make a specialty of fitting up tents

A Day's Record near Parry Sound.

and camping outfits for parties. During the open season the inducements to the hunter are very strong, as the section within an eight-mile radius of Point Au Baril is one of the richest game lands in the country.

The canoe trips are innumerable, and a party can set out and, with portages, return, without having traversed the same waters twice.

The whole country between the Muskoka Lakes and Sudbury is a natural heritage which is becoming more popular yearly, as vacationists return from a happy visit bringing with them stories of the joys to be found among its waters and its woods.

Book Reviews

BIOCHEMIC DRUG ASSAY METHODS WITH SPECIAL REFERENCE TO THE PHARMACODYNAMIC STANDARDIZATION OF DRUGS. By Paul S. Pittenger, Ph. G., Ph. C., Phar. D., Instructor of Pharmacodynamics, Departments of Pharmacy and Chemistry, Medico-Chirurgical College, Philadelphia; Member of Committee on Physiological Testing of the American Pharmaceutical Association, Member of the American Chemical Society, American Pharmaceutical Association, etc., Philadelphia; P. Blakiston's Son & Co.

This manual has been prepared for the use of students of pharmacy, pharmaceutical chemistry and medicine, and pharmacologic experts. It represents a very large amount of original work, and is especially valuable for teaching purposes. The illustrations, many of which are original, are exceptionally good.

The subject matter embraces preliminary considerations, cardiac stimulants and depressants, epinephrine and products of the suprarenal gland, ergot, pituitary extracts, cannabis indica, technique and apparatus and solutions employed.

The manual is an admirable exposition upon a branch of work that has become of the greatest importance in pharmacy—pharmacologic standardization,—and the author deserves to be congratulated upon it.

The importance of pharmacologic standardization does not need to be discussed before pharmacists, for most of them are well aware that this is the only way that reliable preparations of certain important drugs can be made. Some unthinking individuals try to minimize the importance of such procedure on the ground of anti-vivisection. Physiologic standardization is the only means of eliminating worthless preparations of a certain class from the market, and it is certain that where human lives are at stake, the sacrifice of a few animals under anesthesia cannot be condemned.

The title of the book, "Biochemic Drug Assay Methods," is open to criticism, because the book is really not a work on biochemistry, but on the pharmacologic standardization of drugs; and the definition given of pharmacology (p. 3) is open to serious criticism because it is obsolete.

The term pharmacology is derived from the two Greek words meaning "medicine" and "discourse," and as formerly used meant "the sum of knowledge regarding medicines." But times change and the meanings of words change with them. "Pharmacology, in the modern and accepted meaning, treats of the action of chemical substances on living tissue—of the changes produced in the structure, composition and function of living bodies by unorganized chemically acting substances not belonging to their natural environment. Pharmacology, therefore, goes a step further than what used to be called physiologic action, in that it aims to furnish the explanation for the changes observed." (Sollmann).

That this definition is the accepted definition of the medical profession of this country to-day is shown by the fact that the American Medical Association uses the title "Section of Pharmacology and Therapeutics" for its section devoted to the study of the action of drugs on tissues, and therapeutics.

TREATISE ON GENERAL AND INDUSTRIAL ORGANIC CHEMISTRY. By Ettore Molinari, Professor of the Luigi Bocconi Commercial University, Milan. Translated from the second Italian edition by Thomas H. Pope, University of Birmingham. Cloth, 770 + xix pages, 506 illustrations. P. Blakiston's Son & Co., Philadelphia, 1913; \$6.00 net.

This new book is a descriptive organic chemistry, written from the standpoint of the technical chemist, and combining descriptions of the organic compounds themselves with the technical applications of each group.

The author's idea is well expressed in the following quotation from the preface: "It does not suffice that the young chemist, about to begin his industrial or teaching career, should have a thorough knowledge, for instance, of the various syntheses and constitutional formulæ of the sugars. He should also be acquainted with at least the general outlines of the industrial processes and *technique* of the manufacture of sugar, beginning with the slicing of the beets and proceeding to the refining and centrifugation of sugar crystals."

The three divisions of the book are General, Derivatives of Methane, and Cyclic Compounds. Part I discusses the purification and analysis of organic compounds and the general theoretical discussions of organic chemistry.

The principal groups discussed in Part II are the hydrocarbons, alcohols, and derivatives, acids and derivatives, carbohydrates; and in Part III hydrocarbons and their immediate oxygen and nitrogen derivatives, aromatic acids, hydrogenated benzene nuclei, condensed nuclei, heterocyclic compounds, coloring agents and fabrics, proteins, glucosides, and other compounds of uncertain composition.

One thing which will detract from the value of the book to the chemist of America is the fact that methods described, costs quoted, and dimensions given are all or nearly all in terms in vogue in Europe. This is largely excusable in a translation when we think of the secrecy which surrounds so many of our present day works, particularly in this country.

Most industrial chemistries are interesting reading, and this book is no exception. Some particularly interesting descriptions are included, among which might be mentioned explosives, the fermentation industries, sugars, and fabrics. The book will find a place in many libraries and should be read with interest by both the theoretical and the practical chemists, and particularly by the young man just out of college, who is just beginning to realize the necessity for correlating his theoretical and practical training.

GEO. D. BEAL.

ANNUAL REPORTS OF THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION. Vol. VI, Jan.-Dec., 1913. Price 25 cents.

This publication should be in the hands of every pharmacist. It contains data of particular interest to them in regard to the various nostrums which have been discussed in the pages of the Journal of the A. M. A. during the past year. Familiarity with the facts therein stated should be effective evidence to convert many misled physicians from the prescribing of nostrums to the use of official preparations. As the methods of analysis used in the examination of these preparations are stated in detail, the manual is of much value to all druggists and others who are interested in the chemical examination of drugs and chemicals.

Papers Presented at the Sixty-First Annual Convention

THE EFFECT OF GEOGRAPHICAL SOURCE ON THE VOLATILE OIL OF HOPS.

FRANK RABAK, CHEMICAL BIOLOGIST, OFFICE OF DRUG-PLANT INVESTIGATIONS,
BUREAU OF PLANT INDUSTRY, U. S. DEPT. OF AGRICULTURE.

Among the many factors which tend to influence the composition of volatile oils, geographical source, with its attending conditions of climate and soil, is of noteworthy importance. It is a generally accepted fact that a close relationship exists between the growth of a plant with the formation of its constituents, and climatic factors such as, heat, light, moisture, dryness and soil conditions. With regard to volatile oils in general, a number of factors may produce variation in aroma or quality. This geographical location may influence the aromatic property of an oil as attested by Jeancard and Satie,¹ who state that the locality in which lavender, thyme, rosemary and roses are grown has considerable effect upon certain constants of the oils. According to Bonnier,² altitude, light, hygrometric conditions and temperature also affect the plant functions and thus affect its composition. Condition of the soil is also important according to Lamothe,³ who states that soil fertilized with superphosphates increases the esters of lavender oil. In experiments with peppermint Charabot and Hebert⁴ have shown that soil treated with fertilizers produce plants richer in esters and odor-bearing compounds.

Since the conditions mentioned affect the composition of a number of volatile oils, it may be easily comprehended that similar effects may be produced on hops grown in separate localities under different conditions. Furthermore, since the effects on other oils have been noted chiefly in the esters or odor-bearing constituents, it is very probable that the volatile oil of hops would suffer like changes in ester content. For the purpose of ascertaining the truth of the above assumption the following investigation was undertaken.

In order to determine whether any differences exist in the volatile oils of hops, the physical and chemical constants were carefully determined. The physical properties, specific gravity, optical rotation, refraction, and solubility in alcohol are most important in revealing differences due to variation in composition.

¹Jeancard, P., and Satie, C. *La Chimie des Parfums* en 1908. *Revue Générale de Chimie pure et appliquée* Tome 12, p. 181, 1909.

²Bonnier, G., *Recherches expérimentales sur l'adaptation des plantes au climat Alpin*. *Annales des Sciences Naturelles Botanique*. Serie 7, Tome 20, p. 217, 1894.

³Lamothe, L., *Lavender and its Oil*. *American Perfumer and Essential Oil Review*. Vol. 3, p. 128, 1908.

⁴Charabot, A., and Hebert, A. *Bulletin du Jardin Colonial*. Vol. 27, 1902, 3rd series, pp. 224-914.

Among the chemical constants the ester value is possibly of the most importance because of its close relationship to the aroma of the oil.

For the purpose of learning whether any constant differences exist in the various hops, it was planned to compare the oils distilled from hops grown in the hop-producing sections of the United States with the oil distilled from an authentic sample of imported hops, all of the samples to be from hops grown during the same season. The sections chosen in the United States were California, Oregon, Washington and New York. The imported hops were from Bohemia.

A comparison of the oils obtained from the hops during a single season would give results which would be valuable in determining differences for that particular season, but it was also important to ascertain whether the same differences occurred from year to year. Therefore the experiments were carried on for several successive seasons and the oils obtained from the hops of any one locality were compared with those from the same locality during these successive years. This procedure permitted an absolutely fair comparison by which similarities or differences in the properties of the oils could be easily followed and fluctuations readily noted.

The usual method of steam distillation was applied for the extraction of the volatile oils from the various samples of hops. The conditions of distillation were practically identical in all cases, each sample being distilled until no more oil was noticeable. The California hops were from Perkins, Cosumne, Ukiah, and Wheatland. The Oregon samples were from Independence, the Washington samples from Chehalis, and the New York samples from near Waterville. All were representative samples of commercial sulphured hops. The imported hops were from Saaz, Bohemia.

THE YIELDS OF OIL FROM VARIOUS HOPS.

The yields of oil from various hops during the four successive seasons are given in the following table:

Yields of Volatile Oil from Various Hops During the Years 1906 to 1909, Inclusive.

Source of Hops.	1906	1907	1908	1909	Average.
	Percent.	Percent.	Percent.	Percent.	Percent.
California:					
Perkins		0.2	0.38	0.43	0.336
Cosumne		0.32	0.24	0.42	0.326
Ukiah		0.23	0.53	0.28	0.346
Wheatland		0.21	0.20	0.44	0.283
Oregon	0.34	0.20	0.32	0.30	0.290
New York	0.32	0.16	0.14	0.15	0.192
Washington			0.36	0.38	0.370
Imported (Saaz).....	0.45	0.32	0.23	0.24	0.310

Considerable variation exists in the yields of oil from the different California hops, not only among the different samples of any one season, but also among the same hops during successive seasons. The average yield of oil from the California hops during the seasons recorded in the table was 0.32 percent.

The Oregon hops which were distilled during the four successive years showed an average oil content of 0.29 percent, which is a trifle less than the average California sample.

The New York hops with an average during the four years of 0.192 percent of oil were noticeably lower in oil content than any of the other hops distilled.

The Washington hops which were distilled only during two seasons appear to possess the highest percentage of oil, the average being 0.37 percent.

The imported hops distilled from the crops of 1906, 1907, 1908, and 1909, showed an average yield of 0.31 percent of oil, considerable change appearing from season to season.

This variability of the oil content may be ascribed to varying conditions of climate and soil as well as to ripeness and drying of the hops, which would affect the formation of the oil in the plant. Slight differences in yield of oil would not necessarily influence the quality since the same proportion of odoriferous constituents may still be present.

PHYSICAL PROPERTIES OF THE VARIOUS HOP OILS.

The physical properties of the oils permit a somewhat better means of comparison. The properties of color, odor and taste, which are apt to disclose only slight differences, are not discussed. The specific gravity, refractive power and solubility, each of which can be accurately measured, are of much greater importance, although even these properties are usually entirely inadequate for detecting any constant differences in the oils. In all cases the oils were too dark to permit making determination of the optical rotation which is often useful in detecting certain differences in composition. The following tabulations show the differences in the physical properties of the various hop oils distilled during the seasons 1907, 1908, and 1909:

*Solubility of 1907 crop determined after two years; 1908 crop determined after one year.

The densities of the California oils bore a close relationship during individual seasons, differing somewhat from season to season. This would seem to indicate that the approximate composition during any one season was about the same in the several oils. The oils with the highest general specific gravity were those from New York hops, which averaged 0.8554 at 24° C. The Washington, imported, Oregon, and California oils followed in order. It is generally acknowledged that the specific gravity is modified by the composition of the oil but it is doubtful whether the differences noted above would cause any remarkable change in the quality of the oil. A high specific gravity would usually be accompanied by a larger percentage of high-boiling constituents and vice versa.

From the table it will be observed that the oils from imported hops possess higher refractive indices than any of the other oils. This again may be due to the presence of a somewhat higher percentage of highly refractive constituents in these oils. The refraction of the oils from the 1907 crop was higher in most cases than that of the two following years, probably because the constants of the oils from this crop were not determined until 1909, showing that a change had taken place in the oils while aging.

The solubility of hop oil is influenced considerably by the percentage of terpenes and sesqui-terpenes present, the presence of which tend to decrease the solubility in alcohol, while high content of oxygenated compounds increases it. Owing to the preponderance of the former in hop oils and the difficulty thereby encountered in obtaining comparative results, a deviation was made from the usual method for determining solubility. One volume of oil was thoroughly shaken with three volumes of 94 percent alcohol in a graduated cylinder after which the resinous insoluble matter was centrifuged. The amount of insoluble matter could then be easily read on the bottom of the cylinder and the amount of dissolved material readily calculated.

Apparently the most soluble oil among the number was the oil from Oregon

hops of the 1909 crop, one volume of this oil dissolving completely in three volumes of 94 percent alcohol, the oil from the 1908 crop being almost as soluble. The Washington and New York oils from the crops of 1908 and 1909 were slightly less soluble than the Oregon oils. The California oils of these two seasons were a trifle less soluble than those from Washington and New York hops, while the imported oils appeared to be the least soluble.

The much lower solubility of the 1907 oils was due to the fact that the determinations were not made until two years after distillation. Although the oils had been kept in well-filled bottles and well-protected from light, decomposition had ensued which resulted in the formation of less soluble constituents thus decreasing the solubility of the oils. This plainly shows the effect of age on the solubility of the oils.

From the results obtained, it would appear that the oils with the highest solubility probably contained a larger percentage of oxygenated compounds and a lower percentage of terpenic compounds than the less soluble oils.

CHEMICAL PROPERTIES OF THE VARIOUS HOP OILS.

In order to make a better comparison of the several oils with regard to their aromatic quality, determinations were made of the acid, ester and saponification numbers.

A number of factors may tend to influence the acid value. Freshly distilled oils are in most instances low in free acidity, while old oils or oils distilled from old material usually possess a larger quantity of free acids. Improper conditions of drying and storing have a tendency to cause changes to take place which result in the formation of free acids and thereby increase the acid numbers.

As previously stated, the ester values of oils are subject to marked changes due to conditions of climate, soil, etc. This value in hop oils may also be affected by conditions under which the material is dried and stored. The stage of growth and development of the plant as influenced by geographical location may also be a strong factor in modifying the ester content.

The saponification number being the sum of the acid and ester numbers should indicate much the same differences, as shown by the ester numbers. A determination of free alcohols in hop oils was not feasible because of the inability to acetylate the oil quantitatively.

The acid, ester and saponification numbers of the oils from the American and foreign hops are recorded as follows:

The Acid, Ester and Saponification Numbers of Hop Oils Distilled During Several Seasons.

Acid Numbers.

Source of Hops.	1906	1907	1908	1909	1910	Average
California:

Washington			52.8	55.3	54.0
Imported (Saaz)	14.1	21.5	37	31.6	23.5	21.5

The oils in order of their average acidity were as follows: New York, Oregon, imported, California, and Washington. In every instance the New York oils showed comparatively high acidity. The average acidity of the New York and Oregon oils was probably somewhat high as it was considerably augmented by the high acid number of the oil from 1906 crop which was distilled from hops which were not fresh as were those from 1907, 1908, and 1909 crops. The oils with lowest acidity were from California and Washington hops, while the imported hops occupied an intermediate position.

The ester numbers revealed most striking similarities and dissimilarities, not only during one season, but for several successive seasons. It was to be expected that the oils from the hops during any one season would show differences but that these same differences should appear during three and four and even five successive seasons was most surprising.

The oils from the imported hops were conspicuous because of the fact that the data for the several seasons showed the ester content to be only about one-half as great as the ester content of the oils from the California, Oregon, Washington and New York hops. Besides the samples recorded, a cold storage sample of Saaz hops of the 1906 crop distilled one year later gave an oil with an ester number of 24. Three samples of imported hops of the 1910 crop, namely, Dauber, Auscher and Oesterreich Gewächs hops, possessed the ester numbers 15.7, 21.3, and 18, respectively. In all nine samples of imported hops from five seasons gave oils with uniformly lower ester content than American hops.

The close relationship of the ester numbers of the California oils during the seasons of 1907, 1908 and 1909, is very evident. The general average ester

number of the California oils was 45.5, as compared with 50.9 for New York, 52.8 for Washington, 58.8 for Oregon, and 23.5 for the imported.

In case of the foreign oils the ester numbers, which are a measure of the odorous constituents, would seem to point to consistently lower content of these compounds.

The saponification numbers which represent the total acids and esters in the oils presented practically the same constant differences and similarities brought out by comparison of the ester numbers.

While it is not known whether the ester numbers would continue lower indefinitely in case of the foreign oils, it may be assumed that such would be the case, since the authentic samples distilled during five seasons showed abnormally low values as compared with the American oils. In a like manner also it may be assumed that the high ester numbers of the American oils would continue indefinitely since they were quite remarkably constant during the seasons in which the experiments were carried on.

THE RELATION OF THE VOLATILE OIL TO THE SOURCE OF THE HOPS.

A comparison of the fractions resulting from the fractionation of each of the above oils both with regard to physical and chemical constants brought out the same relationships as were shown to exist in the oils themselves. It is, of course, impossible to discuss these results in detail in the short space of this paper. However, from the data presented it is clearly evident that the geographical source of hops has a pronounced effect upon the volatile oil and particularly upon the ester content. The differences noted in the oils appear to be fairly constant from season to season, not only in the physical properties but also in the more important chemical properties. Not only do hops of foreign origin produce oils noticeably dissimilar in some of their properties from the American oils, but hops grown even in separated sections of the United States yield oils with more or less constant differences from year to year. In general, it may be stated with some degree of certainty that the geographical source of hops exerts a decided influence upon the composition of the oils, especially as regards the ester content. Furthermore, it seems highly probable that the geographical source of hops may be indicated by the ester numbers of the oil distilled from the hops since the experiments have shown that the ester numbers of the oils from hops of any particular source or season are very similar.

THE PHYSIOLOGICAL ACTIVITY OF "ERGOTIN" AND POWDERED EXTRACT OF ERGOT.

CHAS. C. HASKELL, B. A., M. D.

There now seems little question as to the therapeutic value of the official fluid extract of ergot. It is sometimes desirable, however, to have solid or semi-solid ergot preparations in a more concentrated form than the crude drug, and it is also often advantageous to secure the active principles in a water-soluble form. These considerations, however, should have no weight, if it is learned that the process of manufacture of such special preparations destroys or greatly lessens the therapeutic activity originally possessed by the crude drug.

Two such "special preparations" have recently been the subject of investigation in this laboratory, and it seems of interest to report the results secured.

The first of these preparations is so-called "Ergotin." It is made by treating powdered ergot with benzin to remove the oils; air drying in order to free from benzin; and percolation with water. The percolate is reduced to a syrupy consistence at 90° to 120° C. and alcohol added. The resulting precipitate is removed by filtration and the filtrate reduced to a semi-solid extract at 90° to 120° C.

The second preparation is a powdered extract made by percolation of ground benzin-extracted ergot with 50 percent alcohol; reduction of percolate to a solid in vacuum dryer and addition of approximately an equal quantity of benzin-treated powdered ergot.

From theoretical considerations, it would seem that little, if any, ergotoxin would be contained in the "ergotin" and what activity it possesses would be due to the amines described by Barger, Dale, Kraft, and others. The powdered extract, however, consists of about one-half powdered drug and the remainder of an alcoholic extract, so one would expect all the active constituents to be present, unless the benzin or the elevated temperature exercised a deleterious influence.

Ergot still finds its chief field of usefulness as an oxytoxic; consequently, any laboratory attempt to estimate the therapeutic efficiency of the drug should be based upon a determination of its oxytoxic power. It has been shown conclusively that a measurement of the pressor-activity of ergot gives no reliable information of the value of the drug as a stimulant to uterine contractions, and it is illogical and useless to make such tests if the drug is to be used in obstetrical practice. It is not improbable, however, that blood-pressure tests upon dogs may give reliable data as to the efficacy of the drug as a circulatory stimulant for man.

The excellent work of Edmunds and Hale has demonstrated that the cock's comb test gives results closely paralleling those secured when the drug is tested upon the uterus of an experimental animal. These authors point out that the cock's comb method is simple and allows of considerable accuracy.

During the past few months, we have had occasion to examine twenty-four samples of crude ergot; four samples of ergotin; and nine samples of powdered extract of ergot. In every instance, when a large enough dose was given intramuscularly to white leghorn cocks, bluing of the comb, diarrhoea and dyspnoea

Figure I. Showing the contractions of a rabbit's uterus after the intravenous injection of Solid Extract of Ergot.

Figure II. Showing the contractions of a rabbit's uterus after the intravenous injection of Po. E. Ergot and of Sol. E. Ergot.

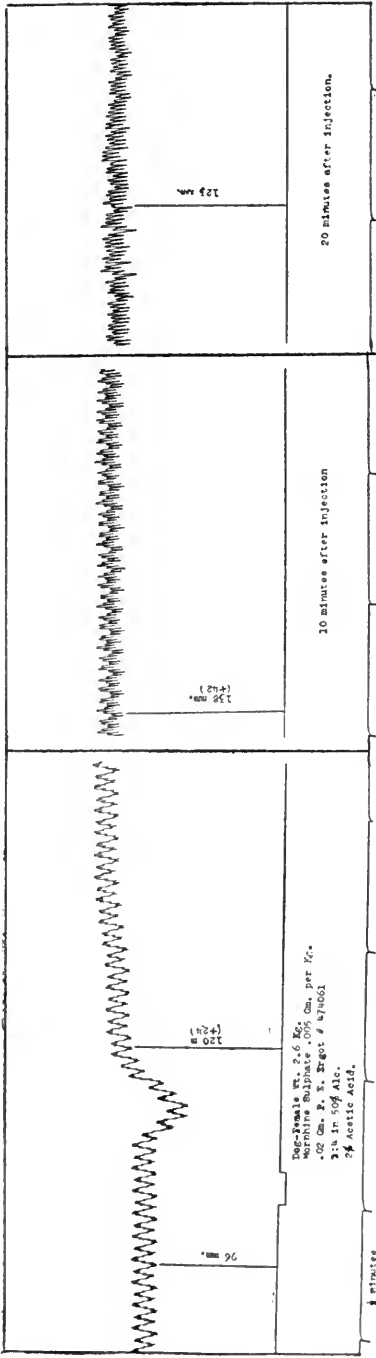

Figure III. Effect of Powdered Extract of Ergot on blood pressure of dog.

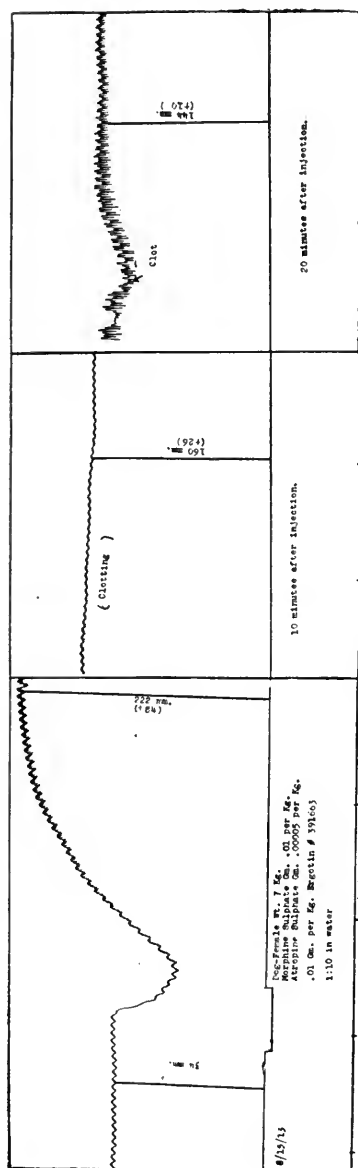

Figure IV. Effect of Ergotin, Bonjean, on blood pressure of dog.

resulted; the symptoms produced by each preparation being practically identical. It seemed desirable, however, to test some of the samples of "ergotin" and powdered extracts upon the uterus of a lower animal. Consequently, rabbits were used in the way described by Cushny, and a marked effect was produced by these preparations in every instance in which they were employed. The tracings, represented in Figures 1 and 2, illustrate the results secured.

These figures do not show the entire records, as the uterus was allowed to return to and remain in, a practically quiescent state for at least one-half hour before the drug was injected.

While feeling that blood-pressure experiments gave no positive information as to the value of the preparations as stimulants of the uterus, nevertheless a number of tests were made upon dogs, using the method of Wood and Hofer, except that 10 mgms. of morphine per kilogram were administered and the dogs also received a small dose of atropine, as suggested by Edmunds and Hale. The following tracings, Figures III and IV, show that these preparations have a marked pressor action.

From the evidence presented, it seems fair to assume that "ergotin" and powdered extract of ergot have the characteristic "ergot" action. It is of interest, however, to learn whether the full amount of drug activity is retained in these preparations.

In the manufacture of "ergotin," approximately six pounds of drug are used to finish one pound of extract. For the powdered extract eight pounds of drug usually furnishes one pound of extract. Consequently, "ergotin" should be six times as active and the powdered extract eight times as active as the crude drug.

Of the twenty-four samples of crude ergot examined by the cock's comb test, all were capable of causing bluing of the comb when given in a dose of 1 gram per kilogram. Of the nine samples of powdered extract examined, a dose of 0.25 gram per kilogram was efficient in all instances. Of the four samples of "ergotin" 0.25 gram per kilogram was efficient in two cases; while 0.3 gram was required in the other two. From this, it seems that the powdered extract is about four times as active as the crude drug; while "ergotin" is, roughly, about three and one-half times as active.

By blood-pressure experiments, however, a different relation is apparent. We have found that 0.1 cc. per kilogram is the optimum dose of fluid extract; that is, this dose usually causes the maximal rise of pressure. With "ergotin," however, the optimum dose seems 0.0125 gram per kilogram; or about one-eighth that of the fluidextract. Cronyn and Henderson have pointed out that large doses of ergot produce poor pressor response, and this is well illustrated by the following tracings, Figures V, VI and VII, where it is seen that with the same preparation of Ergotin (No. 391663) a small injection of 0.01 gm. per kilogram sustains an increased blood pressure much better than does an injection of 0.025 or of 0.05 gm. per kilogram. In fact the blood pressure twenty minutes after the injection of 0.05 gm. per kilogram is actually below its initial pressure. This may serve to explain the poor results that have been secured by others in testing the pressor action of these preparations.

In conclusion it may be said that:

1. "Ergotin" and powdered extract of ergot are capable of causing bluing of

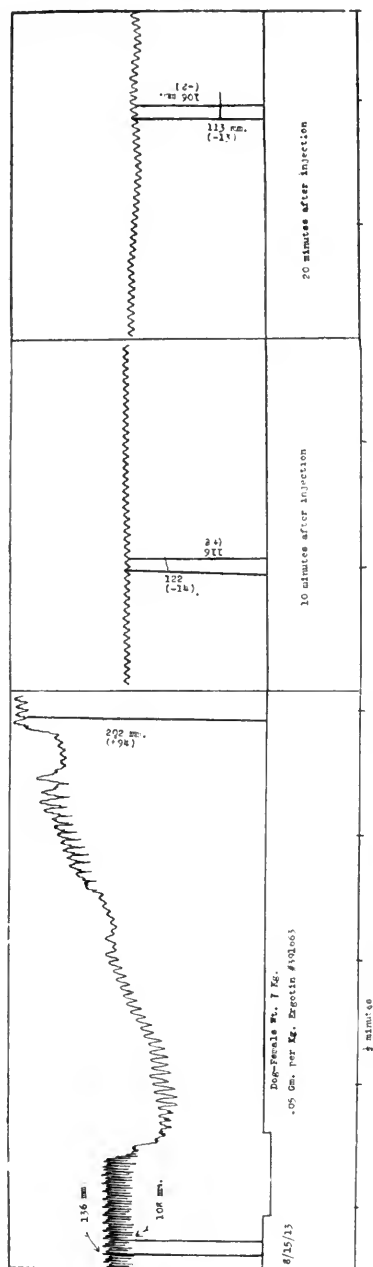

Figure VII. Effect of Ergotin, Bonjean, in large amount on blood pressure of dog.

the cock's comb; contraction of the rabbit's uterus; and rise of the dog's blood-pressure.

2. There is apparently a considerable loss in the manufacture of these preparations, of those substances influencing the uterine movements, while there is but slight loss in the pressor-activity originally possessed by the crude ergot.

DEPARTMENT OF EXPERIMENTAL MEDICINE, ELI LILLY & Co., Indianapolis.

STERILIZATION.

A. PARKER HITCHENS, M. D., GLENOLDEN, PA.

A knowledge of sterilization is becoming more and more important to the pharmaceutical profession as the administration of medicines by the sub-cutaneous and intravenous routes increases in popularity.

The purpose of sterilization in pharmacy is to destroy such forms of microbic life as may exist in medicinal preparations and the various containers, etc., used in handling and dispensing them. Of the innumerable living things that may be found in crude drugs, only the microscopic forms, such as yeasts, molds and bacteria usually escape elimination in the course of manufacture. It is necessary to destroy molds and yeasts, because their growth may result in fermentation or other forms of decomposition, with deterioration, and the production of harmful by-products; but far greater in importance, are the bacteria, which have an additional property only rarely exhibited by yeasts and molds—that of multiplying in the animal body and causing disease.

These microscopic organisms are ubiquitous in nature; one can think of few places where they may not be found. Some of them will grow only upon living tissues (parasites), others will grow only upon dead matter (saprophytes). There are a few species which seem able to multiply even in distilled water, depending upon gases absorbed from the air for their nourishment. Some of the bacteria die quickly when removed from media favorable to their growth, others are so tenacious of life that they may exist for years and possibly for centuries in unfavorable surroundings.

In considering the problems of sterilization it is these latter bacteria to which we are compelled to give especial attention. When organisms of this class find themselves in a medium unsuited to their rapid growth, they go into a state that may be considered a kind of hibernation. The vital part of the bacterial cell is collected within a very resistant capsule, which, with its contents, is known as a spore. The spore state is not a means of reproduction in the sense of multiplication, it is merely a means of self-preservation. One bacillus makes one spore, and one spore makes one bacillus. Therefore, while spores are like seeds in preserving the essential vitality of the cell, they differ in that seed formation is chiefly a reproductive (multiplying) function.

Some spores are able to withstand heat to the boiling point of water for several hours, while bacteria not in the spore state are killed when heated to 60° C. for less than one hour. This difference in the degrees of heat required for killing spores and bacteria, also holds with regard to other germicidal influences. Spores are far more resistant, to phenol for instance, than are non-sporogenic bacteria. The state of the preparation to be sterilized with regard to moisture, is of great importance, since bacteria which are entirely dry may be heated to very far beyond the boiling point of water without killing them, an important point in discussing methods for sterilizing tablets and powders.

Fortunately there are few common sporogenic bacteria which cause disease if they gain entrance to the uninjured intestinal tract.

Whether a remedy is to be administered upon the unbroken skin or mucous membranes, or enterally, that is by mouth or by rectum, or parenterally, under the skin or into a vein—these differences are of fundamental importance. For local application or enteral administration, approximate sterility is usually sufficient, but for parenteral injection or for use in a surgical operation, complete asepsis is requisite. For instance, the tetanus bacillus taken by mouth, is not likely to do any harm, but injected beneath the skin, will, under favorable circumstances, cause tetanus or lock-jaw. By the term parenteral injection is meant, as I have just indicated, the internal administration of a remedy by other than the gastro-intestinal route, that is sub-cutaneously, intravenously, intra-peritoneally, intramuscularly, intraspinally, etc.

Unless remedies intended for local or enteral administration are suspected to contain disease-producing bacteria, sterilization is not generally thought of in connection with them, except in so far as it concerns their preservation. For this purpose the addition of chemical substances is simpler, and since their action is continuous they are more efficient than heat or filtration. This is well exemplified by the fact that, with few exceptions, pharmaceutical preparations, e. g., tinctures, fluid extracts, syrups, etc., contain sufficient alcohol, sugar or other preservative to prevent decomposition through bacterial growth. It is thus apparent that the chief concern we have with sterilization is the preparation of remedies intended for parenteral use.

By sterilization we mean the destruction or removal of every form of reproductive life. To accomplish this we have several methods, physical, chemical and mechanical. The physical methods are heat, electricity and light,—sunlight, ultra-violet rays, etc.

Chemical sterilization is accomplished by the use of such substances as phenol, corrosive sublimate, etc.

The mechanical methods for sterilization of greatest service are filtration, and centrifugation.

Heat. The *naked flame* may be used for sterilizing certain instruments, platinum vessels, spatulas, and small pieces of glassware. A Bunsen burner is generally used for this purpose.

Dry heat may be used for the sterilization of glass bottles, and other glass vessels of various kinds, for powders that are not injured by a high degree of heat, and, where an autoclave is not available, for the sterilization of cotton. It cannot be used for organic or volatile substances or for aqueous solutions. To prepare them for sterilization, bottles and flasks are stoppered with cotton and, as an extra precaution, they may have a piece of paper tied over their mouths before being placed in the oven. They must be perfectly dry. Other pieces of glassware may be wrapped in filter paper or in ordinary Manila paper.

The best arrangement for sterilizing by dry heat is the dry-wall sterilizer of the Lautenschlager pattern. This is a special laboratory apparatus heated by gas, with the walls so arranged that the hot air is kept in motion and approximately, the same heat is maintained in all parts of the oven. A small dry-wall sterilizer is not expensive, but, since the desired heat may be obtained in an ordinary bake-oven, it is likely that in pharmacies, where a great deal of work requiring sterilization is not done, the pharmacist will use the kitchen range, and

he may do so with perfect safety. For small pieces of glassware it is the rule to consider sterilization accomplished when the paper wrapping has started to char. A precaution that must be noted, however is, that, if the oven is extremely hot, the paper may char almost immediately, before the heat has had time to penetrate to the vessel. In using the dry-wall sterilizer, it is customary to run the heat up to 180°C ., and continue it at this point for two hours.

Steam and boiling: The method which has by far the widest field of application is sterilization by steam. There are two methods: (1) by steam under pressure in a closed chamber called an autoclave, (2) by a double walled hood, in which materials are subjected to streaming steam without pressure.

Steam has much greater penetrating power than dry air. Bacteria entirely dry are sometimes not killed even by heating them to a temperature of 150°C ., while all bacteria are destroyed in steam under pressure at 120°C . The best apparatus for sterilizing in streaming steam is the Arnold sterilizer. This consists of a pan with a thin false bottom into which water flows and comes in contact with the heat in such a thin layer that it is almost immediately converted into steam. As the steam passes up through the central opening, water trickles down through small holes at the corners of the pan. The sterilizing chamber has a double wall, which helps to conserve the heat. The inside chamber is maintained at a temperature of about 100°C . for at least twenty minutes after the materials being sterilized have reached this temperature. Such a temperature is not sufficient to kill spores and in order to destroy them the "Tyndall," or discontinuous method, must be used. That is to say, substances to be sterilized by streaming steam are heated for twenty minutes on three successive days. The idea is that all active bacteria are killed on the first day; during the period after heating, until the next day, if there is any nourishment present, the spores develop into bacteria and are killed at the second heating. Any spores that may have escaped the second heating are pretty certain to have developed by and will be killed on the third day. While this is the explanation given by some writers, others think that the spores are gradually weakened by the repeated heating, until they are finally destroyed completely on the third day. Fluids that will not stand the temperature of the autoclave, but which will stand boiling may be efficiently sterilized in the Arnold sterilizer by the discontinuous method, provided they contain sufficient nutrient material to favor the development of any possible spores, otherwise the method may fail and filtration, with or without the use of an antiseptic, must be employed. The pharmacist who does not have this special apparatus, can secure the same result if the bottles or flasks containing the fluid to be sterilized are placed in water in a covered vessel, such as a wash boiler or a covered saucepan. The vessels containing the fluid to be sterilized should be raised from the bottom of the pot by a piece of woven wire or something of the kind, and their tops should be well protected so that the cotton stoppers will not get wet.

A still simpler method is to place the fluid in an Erlenmeyer or Florentine flask, which has been sterilized by dry heat, and boil it for fifteen to twenty minutes over the naked flame on three successive days. This method is open to the objection that there is considerable evaporation and therefore it cannot be used if the original bulk of the fluid must be maintained. If there is no objection to it,

a surface coating of liquid paraffin will prevent evaporation, unless the boiling is too vigorous.

It is well known that the boiling point of mineral oils is much greater than the boiling point of water. These may be sterilized by heating them over the naked flame, to 160° C., in a suitable flask.

Steam, under pressure in a closed chamber, known as an autoclave, is the most useful means for sterilizing the ordinary culture media employed in bacteriological laboratories. This is the best method for sterilizing dressings, physiological saline solution, and other fluids not injured by the autoclave temperature. For sterilization in the autoclave, the temperature is maintained at 115° C. to 120° C. under a pressure of from ten to fifteen pounds for twenty to forty minutes.

Fluids not intended for parenteral administration, such as foods of various kinds, that may be contaminated by disease-producing bacteria, are efficiently sterilized by Pasteurization. This is accomplished by heating to a temperature of at least 60° C. maintained for one-half to one hour, the time depending upon the degree of heat used. A temperature so low as 56° C. is sufficient to kill many non-sporogenic bacteria and substances destroyed by a degree of heat greater than this, may usually be sterilized by subjecting them to this temperature, for about one-half hour, from five to seven successive days. In some laboratories the blood serum mixture used for the diagnosis of diphtheria is sterilized by this method.

Sterilization of Fluids in Sealed Capsules: It is possible for the pharmacist to dispense solutions efficiently sterilized, without the use of any apparatus other than a vessel that may be used as a water bath. The solutions that are to be dispensed, however, must be placed in glass containers hermetically sealed—the most useful form being the bottle with a long narrow neck commonly called an ampoule. These, stoppered with cotton and wrapped in paper, or placed in a metal box, are sterilized by dry heat, maintained at 180° C. for two hours. After the fluid to be dispensed is filled into them, through a narrow tube or by vacuum, the necks of the ampoules are sealed in a blow-pipe flame. They may then be sterilized at any temperature their contents will withstand. For instance if it is a question of a cocain solution, the ampoules may be heated to about 60° C. for one hour on seven successive days, at the end of which time they should be sterile—cocain hydrochlorid is said to withstand a temperature of 70° C. without decomposing. If the substance in solution will withstand 100° C., the ampoules may be boiled for one-half to one hour on three successive days. Should a higher temperature be unobjectionable, the autoclave conditions may be obtained by the use of a strong solution of calcium chlorid or other salt in the water bath or one may use a mineral oil. If liquid paraffin is used the ampoules are easily cleansed after sterilization by rinsing them in ether.

Chemical Methods: The chemical methods for sterilization include the use of the well-known germicides, such as bichloride and oxycyanide of mercury, carbolic acid, liquor cresolis comp., formaldehyde, etc. There are times when solutions of these may be used in such strength that they will efficiently sterilize the substances in question. In by far the greater majority of instances, however, they can be added only in antiseptic strength, thus being used merely as preservatives. Cresol, the substance employed at present in practically all laboratories

as a preservative for biological materia medica, is used in various strengths ranging from 0.2 of 1 percent to 0.5 of 1 per cent combined with filtration for serums. In this strength it is only antiseptic. It does not become germicidal until we reach the minimum concentration in water of 2 percent, and even then considerable time must be allowed for its action upon spores. The sterilization of glass vessels, by allowing a strong disinfectant to remain in them cannot be recommended. Tiny scratches and fractures may still be large enough to protect bacteria, since capillary attraction might prevent the solution from coming in contact with them.

There are many well-known substances which are practically without germicidal value but which are efficient as antiseptics. These include boric and salicylic acids, camphor, thymol, etc. Glycerin in high concentration is quite efficient. Sugar is an efficient preservative and is widely used as such, especially in preserved foods.

Filtration: Properly used, and with an appreciation of its limitations, filtration is a method for sterilizing which may be of great value to the pharmacist, for the reason that by this means solutions may be freed from bacteria without the slightest change in their chemical composition. Filtration, of course, cannot be used for thick or syrupy liquids, nor can it be used for suspensions or emulsions of any kind. Many ingenious arrangements have been devised for the filtration of solutions required to be sterile. Some of these combine, in the apparatus, both filtering and filling devices.

Contamination After Sterilization: After a piece of apparatus or a preparation has been efficiently sterilized, proper precaution must be taken to prevent subsequent contamination. There are bacteria not only on *every object* with which it may come in contact, but also in the air. Consequently, if it be left uncovered, except under special conditions, contamination is almost certain to result. When fluids are transferred from one bottle or flask to another, the exposed part of the lip over which the fluid will run, must first be sterilized in the Bunsen flame. Such operations must be done only in specially constructed and protected rooms or under sterile or dust-proof hoods or other covers.

When a sterile fluid has been obtained in bulk, transferring it into smaller containers is one of the interesting problems confronting those responsible for the preparation of antitoxins and vaccines. Such operations must be carried on in specially prepared rooms or under dust-proof hoods. An ingenious and convenient substitute is the oven, as suggested by Professor Cook, or one may use a box lined with blotting paper saturated with a disinfectant solution. If one is expert, the transference may be made by pouring or by means of a sterile bulb pipette. These procedures are suitable for small quantities but for large amounts it is customary to use a graduated burette or a special contrivance, of which there are many on the market. In my experience a properly arranged burette is the most satisfactory filling apparatus for general purposes. In one of the larger manufacturing biological laboratories the filling of serums and vaccines is done in special rooms which are furnished with washed and filtered air. The rooms are disinfected with formaldehyde at least once a week and the operatives wear sterilized gowns and caps.

Tests for Sterility: In spite of the most approved *technique* and the most efficient apparatus, it may never be taken for granted that a fluid has been freed from living bacteria and has remained sterile throughout the process without proper bacteriologic controls. These controls must be such that they will meet every peculiar condition likely to influence the growth of bacteria in the solution. We read frequently of persons who make control cultures by placing a drop of the fluid upon nutrient agar—a solid culture medium. Sometimes fluids tested in this way, contain sufficient antiseptic to prevent the growth of bacteria which are present. This method is therefore faulty. Control tests must be made in a fluid medium, and the bulk of fluid must be sufficient to dilute the antiseptic contained in the substance under examination to such an extent that it can have no possible antiseptic power.

The contaminating bacterium may be an aerobe (i. e., one that requires oxygen for its growth) or it may be an anaerobe (one that requires the absence of oxygen). The control culture must afford conditions for the growth of bacteria of both kinds or two sets of controls must be made. Fortunately the latter is not necessary because the common fermentation tube affords conditions suitable for the growth of both varieties. The necessary condition is that the *bouillon* must have been freshly sterilized in order to drive off suspended or dissolved oxygen since this would prevent the growth of anerobic bacteria. After shaking the bottle containing the substance to be tested, to be sure that any contained bacteria are distributed throughout, a small quantity of the fluid is withdrawn with a sterile pipette and transferred to the freshly sterilized fermentation tube. Bacteria present may be slow growers and their presence may not be recognized even after twenty-four hours incubation. The reading should not, therefore, be taken earlier than forty-eight hours after the control culture has been made. Bacterial growth of any kind should be sufficient to cause the material to be withheld.

If the substance under examination is one that may possibly be contaminated by the tetanus bacillus, that is to say, if it is a nutrient fluid or a biological product that has been developed upon nutrient media, or if it is the serum of an animal which might have had tetanus toxin in its blood at the time of bleeding or if in any other way toxic or harmful substances might have gained entrance to it, a cultural test is not sufficient. A quantity, at least relatively equal to the maximum dose that may be used for the patient, should be injected into an animal and the effects of the injection on the animal observed for a sufficient length of time to detect the results of a possible harmful contamination.

Those who have had much experience in the preparation of substances intended for subcutaneous administration, are familiar with the many sources of danger and know of so many instances of serious errors that they are inclined to make too many controls rather than too few. In the larger biological laboratories it is customary to have each product tested in bulk, by two bacteriologists working independently. Products that have passed this test are filled into proper receptacles by means of a carefully sterilized burette or other filling device. Cultural tests are made of the filling device before any filling is done, and a number of filled containers selected at random are examined bacteriologically to be certain the filling has been done properly. In addition to this the special rooms above mentioned are set aside for the filling, and these are given unusual care.

It is evident that if remedies intended for parenteral administration are to be dispensed only after passing through the rigorous tests mentioned above, they must be prepared by persons who have had training in bacteriological *technique*. A realization of this fact is leading the colleges of pharmacy to give their students advanced training in special bacteriological *technique*. To be useful such courses should be thorough. It is apparent that here a little knowledge might be a dangerous thing indeed. Certain criticisms of the tests suggested for the preparation of remedies for parenteral administration will undoubtedly be made. Some persons will say, many others will think, that we have been getting along all these years with much simpler methods—why not continue? The reason we may not continue with them is that these simpler methods are the cause of serious and even fatal infections. We learn of some of them, there are probably ten times as many that we never hear about. The demand for sterile solutions for hypodermic and intravenous injection is destined to increase, these solutions must be sterile and their sterility must, before use, be demonstrated by adequate tests.

THE MULFORD BIOLOGICAL LABORATORIES, Glenolden, Pa.

DISCUSSION.

M. I. Wilbert, of Washington, D. C., said that, from a pharmaceutical point of view, he believed Dr. Hitchens had demonstrated clearly and fully that the only safe and reliable method of sterilization was the very simple one outlined in the German Pharmacopoeia: "Sterilization should be done in accordance with established bacteriological *technique*." That was the only safe method of sterilization. It was absolutely unsafe to follow any published prescription or formula. Discontinued sterilization was often spoken of as being absolutely safe, but it was not. In connection with solutions that were themselves antiseptic, like physiological salt solution, if the substance were contaminated by spore-bearing organisms, it could be sterilized half a dozen times, and still be extremely dangerous. Discontinued sterilization depended largely on the development of spores into viable organisms, recognizing that spores themselves are not affected at the ordinary temperatures used. Therefore, ordinary sterilization, unless at very high temperature, would have no effect. Sterilization at high temperatures was not without possible dangers. Repeated work on distilled water had shown that this form of water afforded favorable conditions for the growth of micro-organisms; and under certain conditions, as had been shown recently, distilled water might contain, after three or four days, a tremendous number of organisms. The use of such a contaminated water is objectionable from every point of view, even if properly sterilized it would involve risks from generated poisons or the killed organisms themselves.

In connection with the possibilities of the sterilization of local anesthetics, a considerable amount of work had been done in Germany; but the field was so large that there was no end to the possibilities in that direction. Cocaine solutions, that Dr. Hitchens had said could be sterilized at 70 degrees, could also be heated to a considerably higher temperature for a very short time. So that with recently distilled water, and satisfactory conditions so far as containers were concerned, solution of cocaine could be heated to even 100 degrees for a few minutes. Such a solution would be reasonably safe; not absolutely safe, but reasonably so. He said Dr. Hitchens had covered so much ground that it was hard to grasp it all at once, but he hoped the members would fully appreciate his first statement, which was that sterilization should only be successfully done with adequate control, and in strict accordance with bacteriological *technique*.

Chairman Havenhill commented that this certainly was a live subject, or soon would be, with pharmacists. He said he understood the next Pharmacopoeia would contain a chapter on sterilization.

E. Fullerton Cook, of Philadelphia, said that one point Dr. Hitchens brought out was worthy of still further emphasis, viz.: that suggestion which made it possible for the phar-

macist to prepare sterile solutions in ampoules with the use of simple apparatus only. He suggests that suitable solutions in non-soluble glass ampoules, may be sterilized after the ampoules are sealed, by placing them in oil or saturated salt solution, and heating for fifteen minutes at a temperature of 115°C . This operation requires only the use of a covered vessel and a thermometer, while the results obtained would approximate those secured through the use of an expensive autoclave; that is, the temperature would be the same as that of the autoclave and the pressure, consequently, inside of each ampoule would be equivalent to the pressure in the autoclave under those conditions.

Such a process is not applicable to all substances, since the temperature required is prohibitive at times, and yet this plan is so simple and where it can be applied so easily and promises such satisfactory results, that it should not be passed over without the emphasis here given.

F. W. Nitardy, of Denver, said his practice was to use steam at 30 pounds pressure in the process of sterilization, keeping it at that point for fifteen minutes. He considered this sufficient sterilization.

Doctor Hitchens, responding to the last speaker, said he thought there was no doubt about the efficiency of this method, provided precautions were taken to have the steam completely replace the air in the chamber. And yet, without control, it would fail. In the ten years he had been doing this work, he had failed many times; but the failure was because somebody had not taken the precaution to remove the air, with the result that the sterilization would not be complete, unless the temperature was raised very high. As he had tried to bring out, and as Mr. Wilbert had kindly emphasized, sterilization must always be controlled by proper cultures. Such cultures are usually made in fermentation-tubes, containing freshly sterilized 2 percent dextrose *bouillon*. With all the precautions ordinarily taken, failure sometimes occurred.

Otto Raubenheimer, of Brooklyn, said he desired to emphasize one point—a thing that should be well known to pharmacists at this time; that distilled water was not necessarily sterile water. Some gentlemen seemed to be of the opinion that sterilization can be attained very easily. But Dr. Hitchens and Mr. Wilbert had properly emphasized the necessity of bacteriological control. He related his observance of a city milk-inspector taking samples of milk for analysis from several milk-wagons, and of the indifference to the exposure of these samples to contamination by bacteria. By the methods pursued by this inspector it must follow that the milk would show excess of bacteria, and he presumed that the milkmen from whom the samples were taken would be disciplined. This incident, he said, would show how carelessly such work is done,—work that should be done with great care and precaution; and all work of sterilization should be guarded with the utmost precaution.

METAL COLLOIDS—THEIR INCREASING IMPORTANCE AS REMEDIAL AGENTS.

CHAS. E. VANDERKLEED AND FRITZ HEIDELBERG.

Perhaps no field of chemical and physical research so well shows how rapidly progress is being made, as a glance at some recent developments in the study of colloids, and particularly at the changes that are being made in our conception of colloids. Just as we no longer believe that atoms are actually indivisible—though for all or nearly all of the purposes of the art of chemistry we may still so consider them; just as we no longer are convinced of the absolute indestructibility of matter—though for all practical purposes in chemistry and mechanics we may so calculate; so do we no longer adhere to Graham's original classification of matter into crystalloids and colloids. We may no longer look upon colloids as a distinct class of substances, separate and apart from other classes

of substances, any more than we can consider gases or liquids or solids as distinct subdivisions of matter. Just as many substances may appear in solid, liquid or gaseous form, so may almost, if not indeed all substances, whether or not they possess the power to crystallize, appear under certain conditions as colloids. In the words of Wolfgang Ostwald in his "Grundriss der Kolloidchemie,"—"Unter geeigneten Bedingungen grundsätzlich alle Stoffe in kolloiden Zustand erscheinen können." (Under certain conditions, fundamentally all substances may appear in colloidal form.) Colloidal chemistry may not therefore be defined as the study of colloidal substances, but rather as the study of the colloidal condition of matter.

The authors of this paper will not presume to enter into a discussion or even a review of the recent theoretical developments of colloidal chemistry and physics. Suffice it to say that to the physicist and student of theoretical chemistry, the subject is of utmost importance and interest. Like radio-activity, the study of the colloidal form of matter may prove to be one of the means of bridging over the gap between matter and energy, while biologic and physiologic chemists may ultimately find in the study of colloids the chemical and physical solution of life itself. Many volumes of researches, discourses, and text-books on the subject have appeared, notable among which may be mentioned, Ostwald's "Grundriss der Kolloidchemie"; "Die Kolloide in Biologie und Medizin," by Bechhold; "Kolloidchemie des Lebens," by Liesegang; and a very interesting little book in English entitled, "An Introduction to the Physics and Chemistry of Colloids," by Hatschek. A monthly journal, the "Zeitschrift für Chemie und Industrie der Kolloide," now in its twelfth volume, has recently been supplemented by an "Ergänzung" called "Kolloidchemische Beihefte,"—all devoted to the development of the theory and practical application of colloids. Ostwald expresses the opinion that such problems as the relationship between color, constitution, molecular form, solvents, etc., may ultimately be solved by the study of colloidal forms of matter.

Neither shall we re-state the well-known, and for practical purposes valuable, classifications of colloids by Graham (1861-1864) into "sols" and "gels"—hydrosols, organosols, and hydrogels,—reversible and irreversible, etc. For the purpose of this paper it is sufficient that we picture the colloidal form merely as a state of exceedingly fine subdivision,—so fine indeed that the individual particles closely approach in size, the minuteness of molecules themselves. Colloidal solutions become then merely a fine suspension of one material in another,—and theoretically we should be able to produce any known substance in the form of a colloidal solution. Such so-called solutions differ, however, from true solutions in that the latter are, so far as physical means permit us to determine, absolutely homogeneous, whereas colloidal solutions are, ultimately, only suspensions, even though the highest power of the microscope may not enable us to see the individual particles. In other words, in the case of a true solution we are dealing with a single phase system as we say in physical chemistry, whereas in the case of a colloidal solution, we are dealing with a two-phase system. If the colloidal particles are solids, they are called "suspensoids"; if liquids, they are termed "emulsoids," owing to their occupying intermediate places, respectively between suspensions of solids and emulsions of liquids,—and true solutions.

Permit us to emphasize the fact, however, that there is no chemical difference between matter in or out of the colloidal form. There is no chemical difference between ordinary mercury and colloidal mercury, any more than there is any chemical difference between ice, water, and steam. Each is in a physically different form, yet all three are water from a chemical point of view. Even the distinction that may be drawn between colloidal and non-colloidal forms of matter by the process of dialysis, does not betoken any chemical difference. Sodium chloride in solution dialyzes because there are no particles present larger than the pores of the parchment, but a solution of glue will not dialyze because the particles of glue in pseudo-solution are too large to pass through. If, however, a dialyzer with larger pores be used,—such for example as a thin collodion bag,—or if a colloid with more finely divided particles than those in the glue be used, this colloid will pass through the dialyzer, though not so rapidly as the crystalloid.

We will understand clearly the nature of a colloidal solution if we consider the changes which occur in an ordinary suspension. If we put sand in water, the sand will settle very quickly to the bottom of the container; if we grind the particles of sand finer, they will still settle completely after being suspended for some time in the water; the finer we grind the sand, the longer it will take for the particles to settle. This is due to the fact that the force of gravity which acts on the particles of sand is counteracted in part by several factors like friction in the liquid, molecular attraction, etc.

Let us imagine now that we are able to grind the particles so fine that this counteraction,—viscosity of the water, molecular attraction, the motion akin to the Brownian movement of very small suspended particles, and the electrical charges with which small particles become endowed,—is equal to the force of gravity tending to bring each particle of sand to the bottom of the container. What is the result? The particles no longer, or at least no longer quickly, fall to the bottom, but remain in suspension in the liquid,—and we thus obtain a colloidal solution,—colloidal sand dissolved in water. In the same way, we can imagine the production of a suspension of sand in oil, where by grinding the sand particles finer and finer, we could finally obtain a colloidal solution of sand in oil. A colloid therefore may be not only water-soluble; it may be oil-soluble, or soluble in any other solvent; and it will depend only on how we choose the medium in which we produce the fine particles, whether the finished product will be water-, alcohol-, or oil-soluble, etc.

Actually, we are not able, by mechanical means, to grind the particles of a substance to such a degree of fineness that we can obtain a colloidal solution, and we therefore have to make use of chemical or of physical (as distinguished from merely mechanical) reactions to get these particles fine enough, although should we have a grinder at our disposal to enable us to grind them sufficiently fine, the resulting colloid would probably be just as good as one obtained by chemical means.¹ Thus, while we are not able to grind sand to a state of colloidal fineness by mechanical means, we can readily prepare a colloidal solution of silicic acid

¹ Colloidal filaments of tantalum, tungsten, etc., are made by grinding the metals to an impalpable powder, mechanically, and then treating them alternately with acid and alkali, when they finally assume colloidal form. But the mechanical grinding alone just falls short of producing the desired result.

by chemical and physical means. It is only necessary to decompose a water-solution of sodium silicate with a slight excess of hydrochloric acid and dialyze the mixture until free from excess of acid and sodium chloride, when there will remain in the dialyzer a perfectly clear, colorless solution of silicic acid.

Such a colloidal solution, in common with other inorganic colloids, is very readily thrown out of the solution or "sol" form, however, on addition of electrolytes, the theory being that these serve to disperse the electric charge with which the colloidal particles are endowed, and which, by its power to enable them to repel each other, helps to maintain the "sol" form. When this charge is dispersed, the particles, no longer antagonistic to each other, aggregate, and soon the whole mass of colloid particles either settles out, or as in case of silicic acid, solidifies to a "gel," enclosing by adsorption the water in which it was suspended.

Colloidal solution of ferric hydroxide, or dialyzed iron, is made by a process analogous to that described for silicic acid,—while colloidal solutions of the metals, such as gold, silver, platinum, copper, and lead, are usually prepared by an electrolytic disintegration method first described by Bredig in 1898. This method consists in passing an electric current, in the form of an arc, between poles of the metal which is desired in colloidal solution, the poles being suspended in the desired liquid, usually water. Under this treatment, particles of the electrodes are broken off in such a fine state of subdivision that they remain suspended in the liquid in colloidal form. Here too, however, the addition of electrolytes soon causes the colloidal metal solutions to precipitate as "gels" which cannot be reconverted into solution-form.

A third method of obtaining inorganic colloids is by reduction. If, for example, we take a solution of a metallic salt like gold chloride, and add a diluted solution of formaldehyde, or any other suitable reducing agent, the gold will be reduced and suspended in colloidal solution if the solution be sufficiently diluted. Again, certain colloids may be prepared by oxidation. If we oxidize hydrogen sulphide gas to sulphur by means of sulphurous acid, the sulphur will assume the colloidal form and remain suspended in colloidal solution.

Just a word as to the probable size of these colloidal particles. First of all, they are so small that they cannot be seen in the ordinary microscope, and as Abbe has shown that the lower limit of visibility is from 800 to 400 millionths of a millimeter, while the wave lengths of light lie between 450 and 760 millionths of a millimeter, it follows that these colloidal particles must be much smaller than these wave lengths themselves. Hence they would forever have remained invisible to the naked eye, had not Zsigmondy and Siedentopf invented the ultra-microscope, which by means of the so-called dark-field illumination, only light reflected or dispersed by the particles, and no direct rays from the source of illumination, enter the microscope. In this way particles calculated to be as small as five millionths of a millimeter can be seen. By a study of so-called "ultra-filtration" methods, Bechhold has passed colloidal particles in solution through filters calculated to have pores not greater than 21 millionths of a millimeter, in diameter, whence it follows that the particles must have been smaller than these pores and hence have at least approached in smallness the limits which have been assigned from other investigations for the diameter of molecules.

According to Dr. Conrad Amberger,¹ the effect of gravity on colloidal particles in suspension is neutralized by the action of the electrical charges when the particles are not greater than 60 millionths of a millimeter in diameter. Since, however, the addition of an electrolyte serves to disperse this electric charge, no inorganic colloid solution would appear to be sufficiently stable for use, for example, in medicine. Fortunately, however, it was long since discovered that by adding a portion of an organic colloid to an inorganic colloidal solution, preferably prior to the formation of the latter, the inorganic colloid is rendered quite immune to the precipitating action of electrolytes. This is probably best explained by Bechhold's theory that the organic colloid, such as glue, gelatin, casein, albumin, etc., forms a layer around the inorganic colloid particle, and as the organic colloids are but little affected by the addition of electrolytes, precipitation is thus prevented. For this reason organic colloids used in connection with inorganic colloidal solutions to prevent precipitation have received the name "protective colloids."

Thus, there is rendered available for use as therapeutic agents, in relatively stable colloidal solution form, many substances otherwise insoluble. If, however, the colloidal state does not necessarily imply a change in chemical composition, of what possible interest can colloids be in medicine? A consideration of this question brings to light first of all the fact that oftentimes very slight changes in a substance may be the means of materially changing its physiologic effect. Substances of like chemical composition, but differing slightly in the atomic arrangement of their molecules, may differ materially in toxicity and in the effects which they produce. Who shall say therefore that a metal for example, or a metallic oxide or hydroxide or salt in colloidal form, may not differ materially in its potency or in its effect from that of its ordinary form? The question of absorbability, the rapidity with which it may be assimilated, plays an enormous part in treatment with medicinal substances. It is not only conceivable, but highly probable, that this rate of assimilation will be entirely different for mercury, for example, in ordinary globular form, though very finely subdivided mechanically, and mercury many thousands of times more finely subdivided in colloidal form. Hatschek in the closing chapter of his little book says, "The study of colloids shows us that the mere subdivision of matter, or, in other words, *the production of large surfaces*, brings into play energies, the effects of which may be of the most varied character, and of the most profound importance."

Moreover, the growth of the art of putting into colloidal form and hence making possible the administration of certain substances in solution or liquid form which otherwise could only be administered if at all in solid form,—and then not hypodermically or intravenously but only by mouth or by external application,—shows at once that there is really a promising field for investigation by the therapist of a new line of materia medica products made possible by new discoveries in the production of colloidal solutions.

Another evidence of the possible therapeutic activity of colloid metals, is their possession of the power of catalytic action so resembling in many ways the action of enzymes that Bredig has called them "inorganic ferments." Exceedingly

¹ Pharmazeutische Zeitung, 58, 1913, p. 188.

dilute solutions of colloidal platinum and osmium will instantaneously decompose very large quantities of hydrogen peroxide into oxygen and water,—while other colloid metals have been used to polymerize fatty oils into hard masses,—powers not possessed by these metals even when subdivided to the highest possible degree by mechanical means.

Nor have physicians been slow to take up this line of investigation. We refer of course to a study of the therapeutic effects of colloidal solutions of metals, oxides, hydroxides, and salts, which in ordinary form are insoluble in water or in other suitable vehicles for their administration. It is hardly to be conceived that any advantage would ensue from the administration in colloidal form of a substance naturally soluble in a suitable solvent. But there remains a large number of substances, of which the metals and some of the non-metallic elements are

A

Ultra-micro-photograph (x1000) of Blue Ointment U. S. P. dil. to 10%.

B

Ultra-micro-photograph (x1000) of Colloidal Mercury Ointment, 10%.

examples, which, unless made “soluble” by rendering them colloidal, must remain unsuitable for use in the materia medica.

Perhaps the first of metal colloids to be introduced into medicine, colloidal ferric hydroxide, or dialyzed iron, is now acknowledged to be a therapeutic failure,—or at least to possess no advantages that are not to be gained from the administration of iron in other forms. This, however, need not deter us from investigating other colloids, for it must be remembered that dialyzed iron was only administered by mouth, and it is probable that slighter differences will be noted between colloidal and non-colloidal forms when thus administered, than when used hypodermically, intramuscularly, or intravenously.

Among the earliest of the metallic colloids to be employed in medicine was silver,—in the form of pseudo-salts with protein and other organic acids,—colloidal in nature, though tried out and used before many of the investigations of colloids had disclosed their real nature. Of undoubted value in the treatment

of certain bacterial diseases from the clinicians' point of view, these colloidal silver preparations possessed little or no direct bactericidal power,—particularly in comparison with solutions of crystalline silver salts. True, they possessed the advantage, much appreciated by the patients, of being non-irritating,—but of what use is a negative advantage unless accompanied by decided positive advantages? Satisfactory, or at least helpful results, however, were consistently claimed by, not a few, but by very many able practitioners. Some explanation other than the possession of antiseptic power must therefore be sought.

Recent investigations of certain French authors (Pastia,¹ Bossani and Marcelet²) have shown that colloid metals influence the opsonic strength of a serum against various bacteria. Bossani and Marcelet think that this influence is not due merely to the colloid nature of the substances, in which case one colloidal metal might act as well as another, but varies with the kind of colloid used.

The experiments of these authors along this line were carried on with the purpose of determining how the action of the leucocytes upon streptococci is influenced by colloidal silver. Experiments were made with animals, men and *in vitro*. The serum used in all the experiments was taken directly before the injection of colloidal silver, one hour after the injection, and 24 hours after the injection.

In the work with rabbits, mixtures were made of serum, a 1:3 suspension of a 24-hour *bouillon* culture of streptococcus, washed white corpuscles, and physiological salt solution. These were incubated for 15 minutes at 30°, slides were made, and from the cocci contained in 100 polymorphonuclear leucocytes mixed with serum there was subtracted the number contained in the leucocytes of the control tubes, namely those in salt solution only.

The results showed that in every case the injection of colloidal silver, while causing no increase after one hour, caused a decided increase of phagocytosis after 24 hours.

Experiments upon people were carried out in the same way and showed practically the same results.

To determine whether the colloidal silver influenced the phagocytic power of the leucocytes directly, or increased the opsonic strength of the serum, a number of experiments were made *in vitro*. Increasing dilutions of colloidal silver were mixed with serum in one series, with physiological salt solution in another, and white blood corpuscles were added to both. Slides made from each series were examined.

The results showed that colloidal silver does influence the leucocytes directly, but the colloid can increase the opsonic strength of the leucocytes only in the presence of serum.

Colloidal mercury and colloidal mercurous chloride have also been introduced into medicine, but have not apparently been used very extensively, the former possibly because of the unstable character of the marketed product. Dimond in

¹ Pastia: La presse medicale 1910.

² Bossani and Marcelet: Gazette des Hopitalz 1908.

a recent article¹ speaks of highly satisfactory results from the injection of colloidal mercury and silver solutions in various infectious diseases, particularly in connection with specific vaccine and serum treatments, and attributes the favorable results to increased phagocytosis. Dimond has used metal colloid solutions both "protected" and "unprotected" by the presence of "Schultz-kolloid," and declares that the use of the latter has not been followed in his experience by any loss of therapeutic activity.

Recently renewed interest in colloidal medication has been aroused, first in France by the use of a form of colloidal copper for the treatment of cancer and tumors, and later by Dr. Leo Loeb in St. Louis, who has reported² on the experimental use both of colloidal copper solutions prepared electrolytically and used intravenously, and of colloidal copper protected with protein substances. His results have been partially successful, and he closes his article in the May, 1913, number of the *Interstate Medical Journal* with these words, "It seems to us necessary, in the interest of science and of practical medicine, to follow to the utmost these lines of investigation."

Following the preparation some time ago of a colloidal silver oxide, our research laboratory has been engaged in a study of the production of other colloids. Renewed interest in the use of mercury by intramuscular injection, usually in the form of "Grey Oil" of the British Pharmaceutical Codex, a mechanically subdivided suspension of mercury in liquid petrolatum and lanoline, suggested to us the advisability of preparing a colloidal mercury soluble in oil, thereby possessing the advantage of stability, if not indeed possessing greater therapeutic activity because of the many thousands of times more highly subdivided nature of the mercury particles.

Such a colloidal solution, containing five percent of colloidal mercury, is here shown, together with a specimen of the ordinary "Grey Oil" diluted also to a five percent strength for the purpose of comparison.

An interesting fact was brought out in our experimental work in preparing these colloids, namely, that the solubility of the resulting product, if protected by a so-called "Schutz-kolloid," depends upon the nature of the "Schutz-kolloid" or protective colloid employed. If, for example, metal colloid be protected by means of a caseinate which is water-soluble, the product will dissolve to a clear solution in water, which may be shaken with petroleum or with chloroform without the latter taking up anything from the water solution. On the other hand, if an oil or chloroform-soluble protective colloid, such for example as lanoline, has been used, the product will dissolve to a clear solution in chloroform, which in turn may be shaken with water without loss of any material to the water layer.

This is here shown by two samples of colloidal selenium, one protected by a water-soluble colloid,—the other by an oil-soluble colloid. Selenium has been used in the form of a selenium-eosin compound by Wassermann in the experimental treatment of cancer,—and this metal has ardent advocates who claim therapeutic virtues for it in many forms. These colloidal forms are now being

¹ *The Practitioner* XCL July, 1913, p. 132.

² *Interstate Medical Journal*, 1913.

³ *Journal of the American Medical Association* LX, June 14, 1913, p. 1857.

tested experimentally and clinically for their possible value in the treatment of malignant growths.

The production of an oil-soluble colloidal mercury also suggested to us the possible advantage of mercurial ointment in colloidal form. Here is shown such a 10 percent ointment, the vehicle consisting of lanoline and petrolatum, and the whole ointment, mercury and all, being soluble in chloroform, unlike ordinary Blue or Mercurial ointment which, when treated with chloroform, separates into a solution of the vehicle and metallic mercury which settles to the bottom of the tube.

We also show herewith ultra-micro-photographs of ordinary mercurial ointment in comparison with 10 percent colloidal mercurial ointment. These photographs, taken with an enlargement of approximately 1000 diameters by means of a dark-field illuminating apparatus, seem to bear out a calculation, based upon a measurement of the particles in the ordinary ointment and the theoretical size of the colloidal particles, that in amounts of the two ointments containing equal weights of mercury, there is approximately 60,000 times as much mercurial sur-

Ointment with lowest possible
illumination.

D
Same as C, but with increased
illumination.

E
Same as C and D, but with
more intense illumination.

face exposed in the colloidal ointment as in the ordinary form. In this connection it is of interest to point out, however, that the individual particles in the colloidal ointment, though theoretically magnified only about 1000 diameters in the photograph, are actually many times smaller than this, due to the fact that to the observer, the particles themselves are luminous and sources of light. Consequently, the brighter the illumination (a high power arc is required), the larger the particles will appear. This is well shown in photographs C, D and E, which represent the same colloidal ointment with gradually increasing intensity of illumination. The particles appear to coalesce into luminous nebulae with increase in luminosity, while if the latter be decreased, the individual character of the particles again becomes discernible. Moreover, no adequate conception of the actual size of the particles can be had, because they are in indescribably rapid motion similar in appearance to the so-called Brownian movement of floating dust particles. Thus each bright spot, as shown particularly well in photograph B, represents not the size of one colloidal particle magnified 1000 times, but rather

the entire circumference of the glow of a particle rapidly vibrating throughout a space very many times its own actual dimensions.

These ointments are also undergoing clinical tests and investigations. It may be of interest, however, to report that the toxicity of colloidal oil-soluble mercury, as determined upon guinea pigs, compared with ordinary metallic mercury appears to be about four times as great. The bactericidal power of water-soluble colloidal mercury has also been determined and appears to be equivalent to a phenol-coefficient of about 27.7.

Here also are samples of water-soluble colloidal copper, protected with casein, and ampoules of the aqueous solution ready for hypodermic or intravenous injection. Each ampoule contains 10 milligrams of substance corresponding to 2 milligrams of metallic copper, this quantity being the minimum lethal dose for 250 gm. guinea pigs. All these metallic colloids have been produced by the reduction method, starting with soluble salts.

Without doubt many things remain to be learned by the employment of these products in medicine, and the earnest co-operation of careful laboratory and clinical investigators along these lines may lead to discoveries of untold importance in the treatment of disease.

RESEARCH LABORATORY OF H. K. MULFORD COMPANY, July 28, 1913.

A PHARMACODYNAMIC STUDY OF THE PITUITARY GLAND WITH TESTS OF A NEW PRODUCT.

FRITZ HEIDELBERG, PAUL S. PITTENGER AND CHARLES E. VANDERKLEED.

The role which the pituitary body or hypophysis plays in life has until recently been a mystery. It was at first thought that its function was to lubricate the nasal cavities. This belief, however, was soon discarded and replaced by the supposition that the gland was, like the appendix, of no use at all. Later, however, it was proven by Vassale and Sacchi,¹ Caselli², and others that the gland plays a very important role and is absolutely necessary to life. It has also been found that acromegaly and other diseases are due to functional disturbances produced by an over or an under secretion of this gland, and that its removal causes death. According to Sajous³ the anterior lobe may prove to be the center of the adrenal system.

The pituitary body varies in size according to the age and species of the animal. The gland most commonly used in therapeutics is that obtained from the ox, and is about $\frac{3}{4}$ inch in diameter.

The gland is composed of two parts or lobes,—the anterior and the posterior or infundibular. The smaller or posterior lobe, which forms only about ten to fifteen percent of the total gland, is the more important therapeutically. This

¹ Vassale and Sacchi: *Rivista Sperimentale de Freniatria* p. 83, 1894.

² Caselli: *Studii anatomici e sperimentali sulla Fisiopatologia della Glandola pituitaria*, 1900.

³ Sajous: *Internal Secretions and the Principles of Medicine*. Vol. 1, p. 216.

lobe contains practically all of the active principles while the anterior lobe is the one which is so necessary to life.

The total pituitary body contains about 80 percent of water, or in other words 100 parts of the fresh gland give about 20 parts of dry substance, containing 2 to 3 parts of the posterior lobe.

Knowledge concerning the chemical composition of the pituitary gland has only recently gained proportions sufficient to warrant the hope that science will ultimately be as successful in isolating and synthesizing its active principle or principles as it has been with the suprarenal gland. Owing to the similarity existing between the physiologic actions of the pituitary and those of the suprarenal gland the theory has been advanced that the active principles of the former will be very similar to epinephrine. In fact it has been shown that the activity of the gland can be concentrated into a basic fraction forming salts with acids. It was possible, however, to split this basic fraction into several fractions of different chemical properties (Fuhner)⁴, which would tend to prove that the action of the pituitary body is due to not one but to the combined actions of

FIGURE 1.—Cut of Prof. Fühner's tracing showing the action of the basic fractions, tested by him, on blood pressure (negative).

several active principles. Schäfer and Vincent⁵ had also shown sometime before that the blood-pressure-raising principle could be divided into two fractions by their different solubilities in alcohol, one containing a pressor and the other a depressor action.

Practically all of the commercial preparations of pituitary on the market are claimed to be extracts of only the posterior lobe. Since the process of separating the posterior from the anterior lobe is both very tedious and expensive, the object of our endeavors has been to isolate from an extract of the whole gland, either a highly active fraction or the active principles themselves. We have also been concerned in endeavoring to differentiate between extracts or solutions claimed to be prepared from certain portions of the gland, and those from the gland as a whole, as we doubt very much whether, in all cases, preparations said to be made from the posterior portion are really not prepared from the gland as a whole.

Physiologic experiments have demonstrated that extracts of this gland are

⁴Fuhner: *Hypophyse deutschen medizinische Wochenschrift*, March, 1913, p. 491.

⁵Schäfer and Vincent: *Journal of Physiology*, May 11, 1899.

valuable therapeutic agents. Thus Magnus and Schäfer⁶ and Schäfer and Herring⁷ have shown that it accelerates diuresis; Oliver and Schäfer⁸ that it is valuable for raising the blood pressure by arterial constriction; Dale⁹, Bell and Hicks¹⁰, and v. Fränkl Hochwart and Fröhlich¹¹ that it excited marked uterine contractions, Ott and Scott¹² that it possesses a rather marked galactagogue action.

The scant knowledge of the chemical composition of the gland and extracts of the same, renders it impossible to ascertain by chemical means the comparative value of two or more extracts or fractions. We are therefore compelled to resort to physiologic assay methods. Of the various physiologic actions of the gland above mentioned there are three which present themselves as possible means of

FIGURE 2.—Cut of Prof. Fühner's tracing showing marked uterine contractions produced by the same preparation which gave negative results by the blood pressure method (See Figure 1).

physiologic standardization, i. e., the action of the blood pressure, the uterus, and the kidneys.

The fact that the blood-pressure method involves the simplest *technique* together with its satisfactory and almost universal use as a means of standardizing epinephrine and suprarenal extracts would at first lead one to believe that this method would also be the most satisfactory one for standardizing pituitary extracts. It has, however, serious disadvantages in case of the latter. As before stated, the blood-pressure-raising principle can be divided into two parts, one

FIGURE 3.—Shows the gradual decrease in the rises in blood pressure produced by repeated injections of equal sizes.

possessing a pressor and the other a depressor action. Prof. Fühner of Frie-burg¹³ has also shown that the sum of the basic principles tested by him caused marked uterine contractions and only a slight pressor action, which was almost completely masked by a marked preliminary depressor action.

Furthermore, extracts which had been deprived of their depressor action by fractionation with alcohol, showed marked pressor effects, while on the other hand they were sometimes almost entirely free from action upon the uterus.

Another serious drawback to the blood-pressure-raising method, is the fact that the active principles of pituitary extract are not nearly as rapidly oxidized as those of the suprarenal gland and therefore repeated injections of equal sizes produce unequal rises,—the subsequent ones generally showing a waning of the pressor action and an increasing prominence of the preliminary depressions.

Still another objection to the blood pressure method is its comparatively low

FIGURE 4.—Tracing showing equal rises in blood pressure from equal amounts of the two extracts mentioned above.

¹³ Hypophyse deutschen medizinische Wochenschrift 1913, No. 11, p. 491.

sensitiveness; in other words, it requires, in most cases, a rather large variation in the size of the injection to produce a variation in the resultant rise. This latter objection is especially serious when comparing two or more samples for research purposes, in which case a mistake of 20 to 30 percent in interpreting the results of an assay may cause a considerable loss of time. For example, we had occasion during our experiments to compare two extracts made by different processes, in order to determine which was the better of the two. According to the blood-pressure method both extracts showed the same activity, while when

FIGURE 5.—Tracing proving the sensitiveness of the uterine method. Chart shows 8 minims of extract No. 1 to be stronger than 12 minims of extract No. 2. By the blood pressure method (owing to its lower sensitiveness) both preparations showed the same activity (See Figure 4).

tested by the uterine method, which is far more sensitive, 8 minims of one extract prove to be more active than 12 minims of the other. (See Figures 4 and 5).

We have had no experience with methods of standardization based upon the diuretic action, but it has been shown by Dale and Laidlaw¹ that this method is also unsatisfactory, due to the tolerance produced by the first injection. They

state that if small doses are used in order to overcome this tolerance "it may be difficult to distinguish genuine effects from the spontaneous variations of urinary flow which occur in almost any experiment, however constant the controllable conditions."

In our experiments upon the isolated uterus we carried out essentially the method of Dale and Laidlaw with a few modifications of the apparatus employed. We used the same apparatus that we employed in our researches upon ergot, as set forth in another paper².

We have used both the uterine and the blood pressure method, during the

FIGURE 9.—Tracing showing the effect of our metallic derivative of the active principles of the whole gland upon the isolated uterus of the virgin guinea pig.

²"A New Uterus Contraction Method of Testing Ergot,—with comparison with the blood pressure method," by Pittenger and Vanderkleed.

past year, throughout all our researches on pituitary substances, and are thoroughly convinced that the uterine method is by far the better of the two. We will not go into a detailed description of the advantages of the uterine method, as our results agree in every instance with the claims made for it by Dale and Laidlaw.

In our experimental work on pituitary extract, we have succeeded in preparing colorless extracts of the *whole gland*, possessing all of the characteristic physiologic properties of the posterior lobe. Such a solution, in sterile ampul form, is here shown, together with tracings, showing the characteristic blood-pressure-raising power, and also the uterus-contracting power, peculiar to the posterior lobe, to a marked degree.

This solution has been prepared as follows: First a watery extract is made of the whole gland. This is then purified by a series of precipitations which deprive the extract of practically all inert proteid substances. This purified extract is then treated with metallic salts of aluminum (or other suitable metals), after which it is neutralized, thus precipitating the metallic derivative. This precipitate is then filtered off, washed, and dried. An aqueous solution of this dried material forms the solution exhibited in the ampoules. The product, therefore, is in reality a solution of a metallic derivative or derivatives of the active principles, in the purification of which, the presence of the relatively inert anterior lobe seems not to interfere, thus permitting of a great saving in the labor and resultant expense of separating the lobes.

We have not yet been able to determine exactly the nature of these metallic derivatives, but are continuing our researches and will give more detailed accounts of further experiments in subsequent papers.

RESEARCH LABORATORY OF H. K. MULFORD COMPANY, August 13, 1913.

VARIATION IN SUSCEPTIBILITY OF THE GUINEA PIG.

(Continuation of a previously reported study.)*

CHAS. E. VANDERKLEED, PHAR. D., AND PAUL S. PITTINGER, PHAR. D.

In a paper read at the 1912 meeting of the American Pharmaceutical Association in Denver, the results of a series of experiments covering one year were given, in which it was shown that the average minimum lethal dose of crystallized strophanthin, Thoms, (ouabain) for 250 gm. guinea pigs, varied during the course of the year from 0.0000511 gm. in September, 1911, to 0.0000844 gm. in May, 1912, the average for the year being 0.0000661, and the extreme variation ranging from 22.7 percent below to 27.7 percent above this average. These experiments having conclusively shown that sex and weight may be dismissed as unimportant, this conclusion having been fully concurred in by other investi-

July, 1913.....	29.5°C.	30.5°C.	0.0000650	0.0000672
Average for two years.....			0.0000665	

A study of this table shows that it is not necessary for us to make any changes in our conclusions of last year's paper. The average M. L. D. for 1911-1912 was 0.0000661 gm.; that for the new series of 1912-1913 was 0.0000672 gm.; while the average for the whole two years was 0.0000665 gm. On the other hand the extreme variations during the new series have been much smaller than those observed during the first twelve months, varying from only 9.8 percent below to 9 percent above, instead of from 22.7 percent below to 27.7 percent above. With less than a 10 percent variation in susceptibility above or below the average, with less than 10 percent of pigs dying or recovering "out of order," we contend that for all practical purposes, the guinea-pig method affords the simplest and most satisfactory means of standardizing the heart tonic group of drugs, at a very reasonably economical cost, without the necessity for standardizing the test animals, and without need for considering seasonal variations. As for the opinion which has been occasionally advanced, that experiments on ouabain really prove nothing as to the possible variation in susceptibility to digitalis or other members of the heart tonic group, we can only say that it would be very difficult to carry out a series of experiments such as we have done, with digitalis, strophanthus or any other drug as a whole. Any variation that might be noted would always cause the question to arise as to possible change in the test material. We can say, however, that in our long experience with this method as a routine one for testing all of the heart tonic drugs, we have found no evidence of any appreciable variation. Moreover, as the physiologic action

of the various heart tonic drugs is very much the same, it is not likely that much variation in susceptibility will be noted. As our opportunities to observe possible variations in the case of vacuum-preserved preparations of digitalis and strophanthus accumulate, we should be able within a year or two more to throw some direct light on this question.

PHYSIOLOGIC LABORATORY OF H. K. MULFORD COMPANY, July 27, 1913.

THE YEAR BOOK OF THE ASSOCIATION.*

Fresh from the hands of the printers comes the first year book of the Association, and, with all modesty, it must be said that it reflects the greatest credit upon the Association and upon all of those by whose painstaking efforts the publication makes such a creditable showing; particularly upon its Editor-in-Chief, our esteemed fellow-member, C. Lewis Diehl, Ph. M. and the General Secretary, Dr. James H. Beal, under whose capable direction the publication has been compiled and printed.

The volume is a distinct addition to pharmaceutical literature, not alone of this country, but of the entire world. Nowhere else can be found so completely and so well, within the limits of a single volume, such an infinite amount of valuable material to the profession, as is comprised in this volume of 621 pages. No pharmacist, who has the true interest of his guild at heart, and who desires to keep "in touch" as to its scientific and its practical progress, can fail to find in this "Year Book," matter not only of the greatest interest, but also much valuable information of distinct and immediate profit. Its value to every pharmacist cannot be stated, except in the most general way;—that there is no druggist but will find in its pages something that he can coin into profit, which will many, many times far exceed the trifling cost of the publication to him, personally. It stands as a conspicuous instance of one of the great advantages of the co-operative work which the American Pharmaceutical Association has done and is still doing for every member of the profession. It is a complete and a perfect answer to the criticism, often expressed by the uninformed, that the A. Ph. A. is ultra-scientific, not practical, etc. In the hands of every pharmacist who reads it and who takes advantage of the information packed into its pages, it will be a most useful,—a most valuable,—aid to him in the conduct of his daily affairs, and studied diligently it will make of him a wiser, better and a higher-class pharmacist and man.

In its typography and general make-up it shows the admirable workmanship, care and capacity of the Stoneman Press of Columbus, with which the readers of the JOURNAL are already so familiar.

THE TABLET INDUSTRY—ITS EVOLUTION AND PRESENT STATUS—THE COMPOSITION OF TABLETS AND METHODS OF ANALYSIS.¹

L. F. KEBLER, PH. C., M. D.²

INTRODUCTION.

It is commonly estimated that from one-fourth to one-third of all the medications in the United States are administered in the form of tablets. Considering the comparatively recent origin of the medicinal tablet, there must be unusual reasons for such a phenomenal growth of the industry. Some of the chief merits claimed for this form of medication, are accuracy, elegance, economy, stability, portability, concentration, rapid solubility, absence of alcohol, comparative safety to the consumer, and convenience for the dispensing physician. If it be correct that machinery, appliances, and manual skill have reached a stage of development whereby it is possible to produce tablets having even a part of such a host of virtues, it would seem reasonable to expect that a very large portion of those found upon the market, should possess the composition claimed for them. It was, therefore, but natural that they should be carefully investigated by the Drug Division. A large number of assorted uncoated tablets, purchased directly and indirectly from manufacturers, were examined. The result did not thoroughly corroborate the general view as to uniformity of composition. Various manufacturers were invited to explain the shortcomings. In some instances they were traced to carelessness on the part of the tablet-machine operator, and in others to ignorance of fundamental conditions, loose methods, uncontrolled conditions, chemical, mechanical, and others, which may all be summed up as a failure to realize the necessity of carefully controlling all steps from the selection of the initial ingredients used in the manufacture of the tablet, to the final chemical examination of the finished product. All these, however, did not yet seem to explain the conditions found in some goods known to be prepared under careful control.

In order to obtain first-hand and full information of the industry, the literature on the subject was fully reviewed, laboratory methods, mechanical, supervisory, and analytical, and other elements were carefully studied throughout the United States. Numerous samples were collected and analyzed. This paper, which embodies the results of this work, covers uncoated tablets only.

¹ The historical portion was read before the Historical Section, and the remainder before the Scientific Section of the American Pharmaceutical Association meeting, held at Nashville in 1913.

² Chief, Drug Division, Bureau of Chemistry, U. S. Department of Agriculture.

HISTORICAL REVIEW OF THE INDUSTRY.

A review of the history of tablet making shows that the two general methods of manufacture, compression and molding, have had somewhat different lines of evolution. In the first method the powdered medicament was given form and compactness by subjecting it to compression in a suitable hand or power press without the addition of any foreign substance to give adhesiveness or bulk, and only substances adapted for compression in this way were employed. Gradually, however, as tablets grew in favor as a mode of administering medicines, it became desirable to compress other drugs, and it was then found necessary to add excipients, to give the ingredients sufficient bulk or adhesiveness, so that at present, while some compressed tablets contain medicaments only, most of those upon the market contain both medicaments and excipients.

In preparing molded tablets, the active drug is usually first mixed with sugar of milk, the mixture made into a suitable mass with liquid, and the paste pressed into molds from which it is subsequently ejected in the form of tablets. Tablets made in this way are usually designated as tablet triturates, but the distinction between them and the compressed tablets, in so far as it depends upon the method of manufacture, has been gradually disappearing, and the tendency is still in that direction.

From this it will readily be seen that there is at present but little real difference between the two processes so far as the essential details are concerned. Some form of adhesive, excipient or lubricant, and some degree of pressure must be used in both cases. These two processes, as well as the resulting products, such as compressed tablets, molded tablets, tablet triturates, hypodermic tablets, dispensary tablets, dosimetric tablets, veterinary tablets, ophthalmic tablets, tablet saturates, etc., will be considered in detail in the following pages.

COMPRESSED TABLETS.

Joseph R. Wood, in his book on tablet manufacture,³ gives the following footnote:

"Stamps have been found in England which have been shown to have been used by the Romans to stamp remedies for producing clearness of vision, or for doing away with dimness of sight. The object aimed at by the medicament was specified in the stamp. It is noteworthy that the stamps so far discovered were designed for remedies for ocular diseases. The preparations were hardened with gum or some viscid substance and were thus ready to be liquefied at any time. Thus our supposedly very modern device of triturates or compressed tablets is only a revival of an ancient Roman custom."—(*American Medicine*.)

Careful search on the part of the author and of the publisher of "American Medicine" failed to locate this statement. Its authenticity could not, therefore, be verified. Lozenges, troches, and pastilles, however, are referred to by a number of early writers.⁴

There is no question that the molding of medicaments was in vogue many years before William Brockedon was granted English Patent No. 9977, December 8, 1843, under the title of "Shaping Pills, Lozenges and Black Lead by Pressure in Dies," and it is equally certain that this invention was the beginning of a great industry. On account of its historical value those portions of the patent and its accompanying illustrations dealing with medicated compressions are here given:

"To all to whom these presents shall come, I, William Brockedon, of Devonshire Street, Queen Square, in the County of Middlesex, Gentleman, send greeting.

"Whereas, Her present most Excellent Majesty Queen Victoria, by Her Letters Patent under the Great Seal of Great Britain, bearing date at Westminster, the eighth day of December, in the seventh year of Her reign, did, for Herself, Her heirs and successors, give and grant unto me, the said William Brockedon, Her special license, full power, sole privilege and authority, that I, the said William Brockedon, my exors, admors, and assigns, or such others as I, the said William Brockedon, my exors, admors, or assigns, should at any time agree with, and no others, from time to time and at all time during the term of years therein expressed, should and lawfully might make, use, exercise and vend, within England, Wales, and the town of Berwick-upon-Tweed, and in the Islands of Jersey, Guernsey, Alderney, Sark and Man, and in all Her said Majesty's Colonies and Plantations abroad, my invention of "Improvements in the Manufacture of Pills and Medicated Lozenges, and in Preparing or Treating Black Lead"; in which said Letters Patent is contained a proviso, that I, the said William Brockedon, shall cause a particular description of the nature of my said invention, and in what manner the same is to be performed, to be inrolled in Her said Majesty's High Court of Chancery within six calendar months next and immediately after the date of the said in part recited Letters Patent, as in and by the same, reference being thereunto had, will more fully and at large appear."

* * * * *

"It is well known that in making pills, and also medicated lozenges, as heretofore practised, the proper materials are mixed with a suitable liquid into a state of stiff paste, which is divided and shaped and allowed to dry, and it is well known that in some cases the gum and other materials, used as adhesive matter for keeping pills and lozenges in form, when the same are mixed by means of fluids, interfere with and prejudice the desired action of the matters employed in making up or preparing pills and lozenges, and these gums and adhesive matters are rendered necessary by the use of fluids for getting the matters into a condition to be shaped. * * * * *

DESCRIPTION.

"Figure 1 shows the section of suitable dies for making pills, and similar dies will be used when making medicated lozenges, but the same would be formed into suitable figures to produce lozenges of the shapes and sizes desired. *a* is the punch of the dies, the lower end being concave; this punch is to be worked by means of a fly press, or by other convenient means. *b* and *c* form the two parts of the lower die. The parts *a*, *b* and *c*, are of steel; and it will be seen that the part *c'* of the lower part *c* of the lower die rises into the part *b* of the lower die, and the part *c'* is sunk to correspond with the punch *a*. It is important that in using the matters in a state of powder or dust, that the successive quantities put into the dies should be (as nearly as may be) of the same weight, and, in order to save the trouble of weighing, I have devised a measuring instrument, which being forced into the prepared powder or dust will take up at each time a regulated measure thereof, and then deposit the same into the lower die. Figures 2 and 3 show two sections of this instrument; in one case the instrument is shown as having just been filled, and in the other figure the instrument is shown as having been emptied. *d* is the handle, which is fixed into the tube *e* by means

of a set screw d' , or by other convenient means, and according as the handle d is less or more into the tube e , so will the quantity measured by the instrument be more or less. f is another tube, which is closed at its lower end; this tube slides freely within the tube e and g is another tube which slides over the outer surface of the tube e ; and the tubes f and g are fixed together by the screw h , which passes through a slot formed in the tube e , which slot allows the tube f, g to slide up and down, the end of the handle d determining the extent of such sliding. When the tube e projects beyond the tubes f and g , as is shown in Figure 2, it is pressed into the powder or dust, by which the end becomes full, taking care that in repeatedly filling the same the dust or powder from which the successive quantities are taken is not beaten down or compressed so as to cause the measure to make a materially greater quantity at one time than another. The measure of powder or dust being thus taken up, is to be deposited into the lower die, b, c , by moving the handle upwards whilst holding the outer tube, g , the pill is then to be finished by causing the punch or upper die d to descend into the die, and thus, by one or more blows, to consolidate the powder or dust. The upper die a , and also the part b of the lower die, is then to be raised up, when the pill may be removed. I have not thought it necessary to show dies for making different shaped medicated lozenges, as a workman acquainted with the making of similar dies for other purposes will readily make the proper punch and lower die to produce the proper size and shape of lozenges desired. It will be proper here to remark that this invention, when making pills, is particularly applicable when using matters readily soluble in the stomach, such as deliquescent salts used medicinally, the carbonates, tartrates and nitrates of soda and potash, and other matters, according to the judgment of the medical man, and the invention is also applicable when less soluble matters are used combined with others readily soluble in the stomach.

"* * * * And I have found that the powder or dust of black lead may be rendered solid with more certainty by means of pressure in dies by withdrawing the air from the dies, and from the powder or dust of black lead therein, before operating by pressure, and such is the case in respect to making pills and medicated lozenges, but owing to the small quantities of matter operated on when making pills and lozenges, I have not in practice found it necessary to exhaust the air in these latter cases. * * * *"

"And I would state that I am aware that clay or brick earth has been formed into bricks, tiles, and other articles, by pressure in dies when in a state of dust or powder, and then burned in kilns, and patents have been granted for such means of making bricks, tiles, and other articles from brick earth or clay and burning; and I mention these manufactures in order to state that I do not claim the rendering powder generally into solid forms by pressure, and then subjecting the same to burning. But I do strictly confine my invention to the following improvements:

"First, I claim the mode of manufacturing pills and medicated lozenges by

FIG. 1

FIG. 2

FIG. 3

causing the materials, when in a state of granulation, dust or powder, to be made into form and solidified by pressure in dies.

"Secondly, I claim the mode of preparing or treating black lead when in a state of powder, granulation, or dust, by pressure in dies, so as to solidify the same.

"In witness whereof, I, the said William Brockedon, have hereunto set my hand and seal, this eighth day of June, in the year of our Lord one thousand eight hundred and forty-four.

"WILLIAM (I. S.) BROCKEDON."

At an early date it was observed that pills made with adhesive material often interfered with and prejudiced the desired action. The underlying object of this invention was to compress medicinal agents in a state of granulation, dust, or powder without the use of gummy matter or other adhesive agents commonly employed in the manufacture of pills and lozenges. The goods made by this process were known for many years as "compressed pills." The patent was put into operation and the pills brought early to the attention of the pharmaceutical profession through the press, as is shown by the following extract⁵:

"We have received a specimen of bi-carbonate of potash compressed into the form of a pill by a process invented by Mr. Brockedon, and for which he has taken out a patent. We understand the process is applicable to the compression of a variety of other substances into a solid mass, without the intervention of gum or other adhesive material. Mr. Brockedon has promised to favour us with a detailed account of this process for publication in an early number."

This note shows that Brockedon put his invention into practical use, and subsequent data corroborate the fact that his goods were continuously on the market, both in England and America, for many years.

Mr. Charles Killgore, one of the pioneers in the manufacture of tablets in the United States, relates⁶ the following incident showing the early importation of "compressed pills" into the United States:

"'Compressed tablets' were commercially imported in 1854 by E. Milhau, a druggist of New York City, at the request of Commodore M. C. Perry, who first procured them in London. The commodore was very anxious to take some of these medicines with him on his trip to Japan. Mr. Milhau did not have this form of medicament in stock and was compelled to place the order abroad, which resulted in considerable delay. The day Commodore Perry received orders to report at Hampton Roads for his final instructions he called on Mr. Milhau and requested that he forward the compressed pills to him if they arrived in time to reach him before sailing. The goods were received in sufficient time to comply with his request."

One of the earliest American druggists to keep Brockedon's goods was Frederick Brown, as shown by the following letters to the writer:

"Philadelphia, Pa., January 8, 1913.

"L. F. Kebler, Chief Drug Division, U. S. Dept. of Agriculture, Washington, D. C.:

"Dear Sir—We were duly in receipt of your favor of December 27, 1912, and have endeavored to find out something definite as to the sale of compressed Potassium Bicarbonate and Sodium Bicarbonate Tablets.

"We regret that we are unable to give you definite information on the subject, as the retail branch of this business was sold in 1888, and we no longer have any

⁵ Pharm. J., 1844, 3; 554. A careful search of the files of the Pharmaceutical Journal failed to reveal a description of the promised process, and it seems likely that Mr. Brockedon never carried out his intention.

⁶ Private communication to the writer.

of the old records. Our treasurer, however, Mr. H. S. Robertson, began the drug business in 1860 with Frederick Brown, Sr., and he well remembers that Brockedon's Compressed Tablets were regularly in stock at that time, being quite actively in demand.

"Regretting that we are unable to give you any further information on the subject, we remain,

"Yours very truly,
(Sgd) "F. ZERBAN BROWN, President."

F. Newberry & Sons, in a letter to the "Chemist and Druggist," given in full further on, state that Brockedon's business was purchased by them in 1871, and they continued to sell his "compressed potass. and soda." Burroughs, Wellcome & Co., in a letter to the "Chemist and Druggist"⁷ write as follows:

"We notice the correspondence (24/27 A. C. S.) with regard to the use of the words 'Tabloids' and 'Tablets' as applied to compressed drugs. The word 'Tablets' was first applied by us to this class of drugs at the commencement of our business in 1878. This form of medication had hitherto been known in this country as 'compressed pills.'"

The following correspondence dealing with historical matters also throws light on the compressed drug industry in England about 1881⁸:

"To the Editor of 'The Chemist and Druggist':

"Sir—Have we in Great Britain any drug manufacturers with sufficient ingenuity to make little pellets or discs of such simple and useful substances as chlorate of potash, carbonate of soda, etc.? If there be such, how is it that a Yankee maker of these articles is permitted quietly, but none the less surely, to establish a monopoly of the 'compressed medicines,' as they are termed in this country?

"'Have you any of these American solid cakes of chlorate of potash?' is already becoming a stereotyped query from our customers. 'My doctor recommends them as so much superior to the lozenges.'

"We are not sure whether the articles in question are strictly a specialty of the wholesale druggist, or the lozenge-maker; but whichever it may be, it is clear that patriotic and selfish motives should combine to determine him to elbow out the intruder. * * * * *

"Bradford, November 5.

"M. ROGERSON & SON."

"To the Editor of 'The Chemist and Druggist':

"Sir—We have observed the letter of your correspondents, Messrs. M. Rogerson & Son, in your last issue, and would point out that the idea of compressing pills or tablets, by whichever name they may be called, was originated by the late Professor Brockedon, the manufacturer of compressed Cumberland leads for lead pencils. He introduced, about twenty or more years since, Brockedon's compressed potass. and soda, which have ever since been on sale both in this country and America. In 1871 we purchased Professor Brockedon's interest in these preparations, and they are still well known at home and abroad. As to 'elbowing out the intruder' it may interest your correspondents to know that we have, since the introduction of the American compressed goods, remarked with satisfaction a steady increase in the demand for the Brockedon's already referred to, and the increase applies as well to foreign as to the home markets. The monopoly must, therefore, exist more in imagination than in reality. * * * * *

"London, November 29."

"F. NEWBERRY & SON.

⁷ Chem. & Drug., 1892, 40: 785.

⁸ Chem. & Drug., 1881, 23: 510.

⁹ Chem. & Drug., 1881, 23: 555

This correspondence shows that Yankee ingenuity and perseverance were making themselves felt in the tablet industry at that early date. The "American solid cakes of chlorate of potash" referred to in the first letter quoted were probably compressed tablets of chlorate of potash and borax, free from any excipient, which were marketed in the United States by John Wyeth & Brother, Philadelphia.¹⁰

The manufacture of "compressed pills" (tablets) in the United States was apparently begun by Jacob Dunton, a wholesale druggist in Philadelphia. He

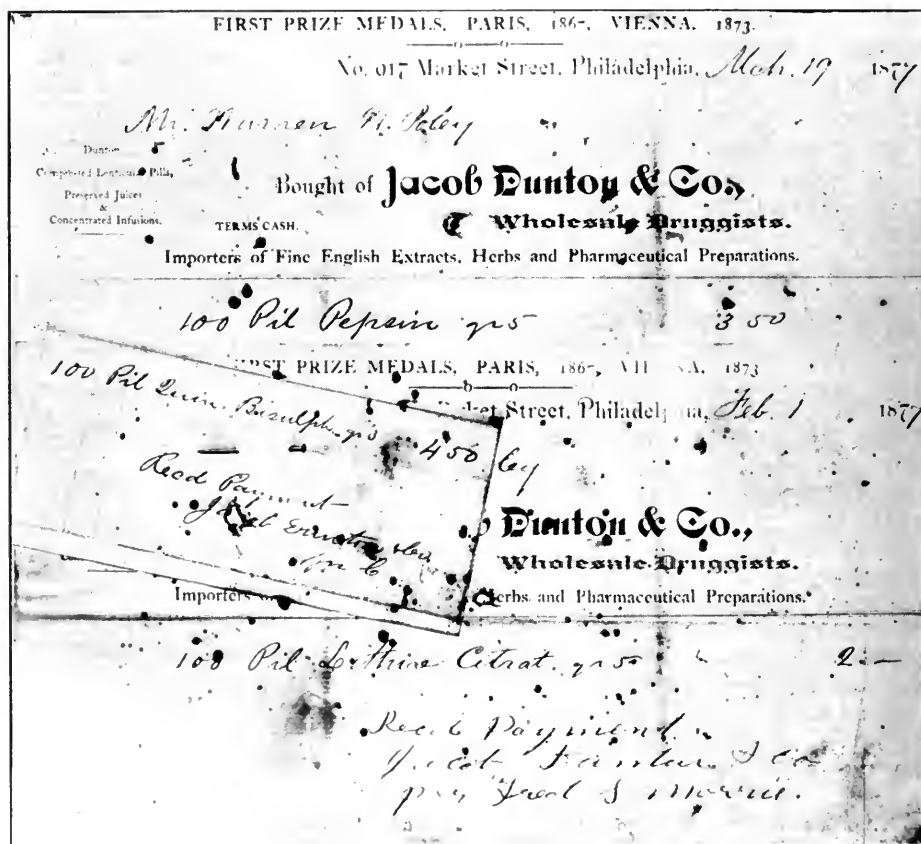

FIG. 4—Dunton's bills. (Furnished by M. Campbell, Philadelphia.)

was graduated from the Philadelphia College of Pharmacy in 1855. A letter from Dr. L. A. Edwards begins thus, "Washington, D. C., August 13th, 1862. My dear Pill-driver et Phot." It would seem that Dunton made "compressed pills" at this early date when they were actually compressed by driving. It is reported that Dunton supplied the United States Government "compressed pills" during the early sixties, but the records are inconclusive. A bill against the United States dated October 3, 1861, includes pills, but the kind of pills is left open. According to the copy of another bill, "compressed lenticular pills" formed a part of Dunton's business as early as 1867, when he was awarded a

¹⁰ New Remedies, April, 1879, p. 2, cover, vol. 8.

Paris prize, but it could not be determined whether the pills were included or not. It is interesting to note from this bill that \$3.50 was charged for 100 pepsin tablets in 1877. There appears to be nothing in Dunton's private effects to throw any light on the time of his beginning pill compression. There is available, however, the complainant's record¹¹ of a litigation, which contains valuable data. On page 8 appears the following:

"Q. Give the date of your (Dunton's) first experiment in this matter, and your employing Mr. Murset.

"A. Some time in the winter of 1863 and 1864; by winter I mean the fall months and the early spring, say March; that was during my stay in the city; I was out of town most of the time from May until November."

On page 5:

"Q. Were you (Murset, a mathematical instrument maker) ever employed by Mr. Jacob Dunton to make a machine similar to that drawing, and if yea, state at what time.

"A. Yes, sir; it was in March, 1864; the beginning of March."

On page 10:

"Q. When did you (Dunton) first put upon the market these compressed pills?

"A. In the fall of 1869."

On page 20:

"Q. I understand from your deposition that you did not put any pills on the market between 1864 and 1869; now I wish to know how many pills you made in that period, and what use you put them to.

"A. Several thousand. I made them up for stock to sell from.

"Q. Do you mean that you made them to put upon the market, but that you did not put them on the market?

"A. I do. The greater portion of these thousand were made in 1869; the latter part of 1869.

"Q. And with what machine were they made?

"A. The second and third spoken of; the second and third machines modified after the machine of 1864."

On page 19:

"Q. Then I understand you (Dunton) now that the lever and the screw and the eccentric were in 1869 adopted and applied by you for compressing the pill or powder?

"A. They were; not on the same machine, however; on different machines.

* * * * *

"Q. I wish to know how soon after 1864 you (Dunton) in any respect modified the machine represented in this Rough Sketch No. 2, and I wish to know at the same time of what the modifications consisted.

"A. I modified the machine described in Rough Sketch No. 2, within two or three years after 1864. The modification in this first machine, modified after the machine of 1864, was by the application of a screw to give power, and the addition of an eccentric to eject the lower plunger or lower die, to eject the pill."

On page 22:

"Q. How many varieties of compressed pills did you (Dunton) make in 1869?

"A. Over three hundred."

On page 21:

"Q. I understand you (Dunton) that you have stated that down to 1876 you had made between two million and three million pills; what machine were they made with?

¹¹ Jacob Dunton vs. Bennett L. Smedley, U. S. Cir. Ct., Eastern Dist. of Penn., in Equity, No. 38, April Session, 1879.

"A. Two and three machines, numbers 2 and 3 spoken of above, and similar machines."

"Q. And none of them were made on the machine patented to you in your patent No. 17490, as I understand you?"

"A. No pills were made for sale on machine patented No. 174790."

This testimony clearly shows that Dunton as early as 1864 had a machine constructed for compressing tablets. It also shows that the machine was modified from time to time and that a patent for one of the machines was applied for and granted March 14, 1876.¹² The apparatus is shown in Figure 5.

The following description of the machine is quoted from the patent:

"This invention relates to an improved machine for making pills by compression; and it consists in a movable or detachable compression-chamber or powder-receptacle, in combination with two movable dies having concaved ends, the upper one of which forms the plunger, and the lower one of which is made short, and is adapted to be driven through a hole in a base piece together with the pill.

FIG. 5—Dunton's pill machine.
Patented March 14, 1876. (Patent
No. 174,790).

"The invention also consists in the construction of the base-piece, which is provided with a hole terminating in a laterally-discharging curved chute, by which the pill and lower die are driven out of the chamber into a convenient position; and it also further consists in the combination, with the powder-receptacle, of the base-piece, provided with guides, which permit the powder-receptacle to be shifted from its position for compressing to its position above the hole for dis-

charging the pill without displacement, and without the delicate adjustment which would be otherwise required.

"In the drawing, A represents the powder-receptacle, which constitutes also the compression-chamber. This receptacle is perforated vertically and longitudinally with a hole, in which are accurately fitted the dies, B B', of which B constitutes the plunger, through which the application of power is made to effect the compression. Both these dies are movable and entirely detachable, and have their adjacent ends concaved, so as to give sphericity to the pills compressed between them. The lower die, B', is made short, and is designed to be driven out with the pill through a hole, in the base piece, C."

It will be observed that this apparatus is very similar to that of Brockedon's compressor. It will be noted furthermore that nothing appears in this patent which would indicate the use of either a lever, screw, eccentric motion or foot-power, instead of hand-power, attachment to lever.

Dunton was apparently the first to secure a process¹³ patent for the preparation of materials to be used in the manufacture of tablets. This patent embodies some of the fundamental principles governing at present. He had noticed that in compressing materials containing the natural moisture of the air the cohesion of the particles was frequently insufficient to produce stability of form. He also observed that the adhesion between the material and the dies and punches was often greater than the cohesion of the particles. The invention con-

¹² U. S. Patent No. 174,790, dated March 14, 1876.

¹³ U. S. Patent No. 168,240, dated Sept. 28, 1875.

sists, first, in drying the material to be compressed in order to expel the natural moisture, thus increasing the cohesion, and, second, in lubricating the die or mold. On account of its historical importance and in order that certain features may be more readily available, portions of the patent are copied herewith:

* * * * *

"In carrying out my invention the powdered materials are first dried, preferably at a temperature of 90° Fahrenheit, so as to deprive them of the natural moisture absorbed from the air, which would have a tendency to decompose them or interfere with the compressibility or stability of compression.

"The materials are now in proper condition for compression and the cohesion of particles. In order to compress, however, such substances as sulphate of quinia, and other substances which leave a portion of themselves adhering to the mold after compression, which adherence prevents the formation and withdrawal of a successive pill of the same material in a perfect or merchantable condition, it becomes necessary to get rid of the adherence, and also to prepare the mold before another pill can be made. The ways which may be adopted are, first, after the pill is made, open the mold and brush out with a stiff brush as much as possible of the adhering particles, and then apply to the surface of the mold a thin film of oil, which takes or soaks up any portion of the particles which is left after brushing, and to get rid of the oil a pill of starch or other equivalent material is made, which absorbs the oil, and leaves the mold in a condition to make another pill of the original material; second, instead of lubricating the mold directly, a small portion of a liquid may be added to the powder (one percent being in some cases sufficient), which under pressure will ooze out at the surface of the pill, and act as a lubricant, so as to allow the pill to be removed from the mold without leaving any particles adhering to the mold, and leaving the latter in fit condition for the next pill."

* * * * *

"In lubricating the mold a portion of paraffin, oil or cacao, butter of cocoa, or other equivalent material may also be used, either alone or in solution in alcohol, benzine, or other volatile liquids, the object being to apply the least quantity that will produce the desired effect, and I may also use an oily or unctuous substance combined with an absorbent material or a material which is of itself both unctuous and absorbent, for cleaning and lubricating the molds."

* * * * *

"In manufacturing pills by compression, the herein-described method of drying the powders, before compression, at a temperature of about 90° Fahrenheit, with 24° absolute dryness (Mason's hygrometer) to prevent reaction upon the mold, and insure stability of cohesion, and lubricating the mold to prevent adhesion, and insure the removal of the pill integrally and perfect."

"Jacob Dunton.

Witnesses: "Lorenzo Westcott,
"Caspar S. Carmell."

FIG. 6—Jacob Dunton.

The samples shown in Figure 7 were obtained from Professor Joseph P. Remington and Henry Blair, of Philadelphia. It will be observed that the name "compressed pills" was applied at that time, but the shape of the medication was that of the tablet as known at present. The exact date when these samples were put on the market could not be established, but the indications are that they are similar to, if not identical with, the tablets put on the market by Dunton in the seventies.

J. R. Wood¹⁴ states that John Wyeth and Brother, in conjunction with Henry Bower, succeeded in producing a "hand press" in 1872, which materially reduced

FIG. 7—Labels and bottles used by Dunton.

the cost of manufacturing tablets. This is corroborated by the following letter, except that the machine does not appear to have been a "hand press":

"Philadelphia, January 14, 1913.

"Mr. L. F. Kebler, Chief, Div. of Drugs,

"U. S. Department of Agriculture, Bureau of Chemistry,

"Washington, D. C.

"Dear Sir: Your letter of the 27th ultimo was duly received and answer was delayed on account of absence of one of our principals and beg to herewith make reply and advise that the articles you have noted published under tablet manufacture and in the Medical Record are correct.

"We have no prepared data or printed matter on hand of tablet compressing machines; from our books we glean that in about 1872 we constructed the first rotary tablet machine in our own shop by our chief mechanic; this machine was what is styled a disc machine with several dies, and improvements were constantly added and machine perfected until we had some machines that had as many as 13 dies in rotating disc and some of these machines are still in use at the present time in our laboratory.

¹⁴ Tablet Manufacture....1906, p. 11.

"We are also the originators of the compressed hypodermic tablets and compressed tablet triturates, also compressed medicinal lozenges; these three variations were introduced by us during a period of 1877 to 1880 and other combinations of compressed tablets followed quickly according to demands made upon us by the physicians and trade. Prior to 1877 the formulæ that were sold in tablet form were very few. They consisted of simple chemicals principally, such as potassium chlorate, ammonium chloride, etc., and after 1877 combinations followed. Physicians saw the convenience of this form of medication and at various times submitted different compound formulæ which were made into either tablets or compressed lozenges. After 1880, tablets having become quite popular, others entered into the manufacture of them, and various machines were invented and improved and are known as single and multiple die machines with shoe feeding devices; also different styles of rotary machines have been made since then.

"We trust this information will be helpful and regret we have no prepared data in detail that we can supply.

"Yours very truly,
(Sgd) "JOHN WYETH & BROTHER,
Incorporated. H."

The following extract from a letter written by Jacob Dunton shows that the manufacture of tablets in the United States was assuming a real trade interest:

"Philadelphia, Jany. 18th, 1876.

"I wish you would lend me a few of 'Wyeth's Compressed Quinine Pills.' I want to examine them. Some I purchased of them contained Cinchonine & I want to examine the lot they sent you.

* * * * *

(Sgd) "JACOB DUNTON."

In conjunction with this correspondence and the great improvements in mechanical apparatus used for compressing tablets, it is interesting to record the fact that there is still in use one of the old power tablet compressing machines made about thirty-five years ago. The exact age of the machine could not be determined, but Mr. Herman Wiph of John Wyeth & Brother, in whose establishment this machine is found, writes, April 29, 1913:

"Please find enclosed one front and one side view of the oldest power tablet compressing machine in existence, as far as I know; and still in use. I have personally been using it for the past 32 years, and it was in existence several years previous to my time. It is therefore about 35 years old, and may be even 40 years old. This machine is used on any size tablet from 1/16 inch to 3/4 inch in diameter, and the pressure can be regulated from the slightest to the most powerful. The material to be compressed is fed into the die, by hand, with German silver ladels or dippers of various sizes, according to the weight of the tablet. The tablet after being compressed is raised above the die level by one of the levers on the right side and is pushed off by the operator with the dipper. The other lever is used to throw the clutch for compressing, the machine making only one revolution, and is then stopped automatically by a brake, until the clutch lever is again thrown in. Only one tablet is compressed at a stroke."

This machine is similar to, if not identical with, the apparatus covered by United States patent, granted to Thomas J. Young in 1874.

Tablet making in Germany seems to have had its beginning in 1872, when Professor Rosenthal, of Erlangen, described his tablet compressor at a session

of the Physicalisch-Medicinische Societät.¹⁵ A translation of a part of the proceedings of the session is as follows:

"Prof. Rosenthal then exhibited an apparatus for the compression of medicinal substances in volume. This machine was originally intended for the administration of Koussou, but may be used for other medicaments also. It converts powdered drugs into small solid tablets, which may be easily swallowed. Ill-tasting

drugs, in volume, or such as must possess exact dosage (*Dosierung*) are by this method made easy to take. The effectiveness of the medicament is in no way injured, as it disintegrates quickly in the stomach and reverts to its original state. This form of dosing has been tested with excellent results in various cases."

FIG. 8—Oldest known tablet machine still in operation. (Wyeth.)

A fuller description of the invention was published in 1874.¹⁶ From this it appears that Rosenthal had no knowledge of Brockedon's invention, but believed his to be the first machine ever devised for the compression of drugs into tablet form. He says:

"Pills, powders and electuaries are still prepared and prescribed in essentially the same way as they were one hundred years ago. * * *

Up to the present time

all previous methods have been insufficient to solve the problem of administering large doses of medicaments offensive to taste and smell, or both."

His method consisted in compressing drugs into tablet form without the addition of foreign matter, so that they might easily be swallowed without offense to taste or smell.

The machine consists of a screw press upon a rectangular stand which may be fastened securely to a work-table or counter with clamps or screws. The iron bed-plate supporting the press has a hole drilled through its center. A slide pierced to admit a ring for a handle can be used to close or open the hole in the bed-plate, by pulling it aside. Upon the bed-plate rests the hollow cylinder *d*,

¹⁵ Sitzungsberichte d. Phys.-Med. Soc. zu Erlangen, 1872, Heft 4 (Stzg vom 3 Juni), p. 70.

¹⁶ Berl. Klin. Wochenschr., 1874, 11: 417.

and in this the powder is placed in the molds, *a*, *b* and *c* (Fig. 9.) When downward pressure is exerted by means of the screw, *e*, the loose powder is compressed into a tablet which, when removed from the cylinder, is ready for immediate use, or may be afterwards coated with gelatine. After the introduction of Rosenthal's machine, which was among the most advanced recorded at the time, the tablet became a recognized form of medication in Germany, but the home industry did not seem to keep pace with that of other countries, as is shown by the fact that English goods made such an impression upon the German public that manufacturers in Germany resorted to the scheme of using English labels to promote the sale of their goods.¹⁷

FIG. 9—Rosenthal press.

The tablet industry, like the coal-tar industry, had its origin in England. Germany, having absorbed the greater part of the coal-tar industry, was reaching out for the tablet business, but not with very satisfactory results. Conditions in Germany were apparently not propitious for the best expansion of the industry, but at any rate, the center of activity was transferred to the United States, which country has held the supremacy for the last quarter of a century.

FIG. 10—J. A. McFerran's rotary machine, U. S. Pat. 152,666, 1874.

The first patent for an automatic "compressed pill" machine was issued to Dr. Joseph A. McFerran, of Philadelphia, in 1874.¹⁸ This was what is known as the intermittent rotating machine, and the idea was probably taken from the cartridge-filling machines which had been in use for a number of years. For some reason the invention did not find proper recognition and the inventor did not receive any material profits. The same year a patent was granted to Thomas J. Young, of Philadelphia,¹⁹ and assigned to Henry Bower, of the same place.

This represents the earliest semi-automatic upright or vertical punch machine. In order to get the details of the

¹⁷ Chem. & Drug., 1888, 32: 712.

¹⁸ U. S. Pat. No. 152666, dated Jun. 30, 1874, appln. filed Jun. 18, 1874.

¹⁹ U. S. Pat. No. 156398, dated Oct. 27, 1874, appln. filed Oct. 8, 1874.

machines it is best to consult the patents themselves. The illustrations and brief descriptions are intended to give only a general idea.

Briefly, McFerran's patent consists of an intermittent rotary disc, with eight dies, an automatic feed, an upper and lower punch and a brush for removing the pills. The upper punch is raised and lowered by means of two beveled cog-wheels with a part of the teeth cut away and a spiral on the punch. The upper and lower punches are reciprocatingly rotated in order to overcome sticking.

Young's machine consists of two punches and a die. The upper punch is raised and lowered by means of an eccentric wheel, and the lower punch is raised

FIG. 11—I. J. Young's vertical machine. U. S. Pat. 156,398, 1874.

by a *cam* on a shaft, transmitting power through a rod and lever, and is lowered by a weight. The press is set in motion by a lever and is automatically stopped at the completion of one revolution. Feeding must be done by hand.

Joseph P. Remington, of Philadelphia, in 1875, described a simple piece of apparatus of the Brockedon type whereby the retail druggist could manufacture his own compressed medicines called for on prescription.²⁰ The method of operation can be readily learned by referring to the original communication.

This apparatus was improved by the inventor in 1876.²¹ The vertical machine alluded to was improved in 1877 by Thomas J. Young²² and this improve-

²⁰ Proc. Am. Pharm. Assoc., 1875, 23: 620.

²² U. S. Pat. No. 189005, dated Mar. 27, 1877, appln. filed Mar. 9, 1877.

ment was assigned to Henry Bower. In 1879 Jabez H. Gill, of Philadelphia, was granted a patent²³ for an improved "compressed pill" machine, which he assigned to Henry Bower. Two years later the same inventor was granted another patent²⁴ which was assigned to John Wyeth & Brother.

It should be noted that there appears to have been some affiliation between Mr. Bower and John Wyeth & Brother. In fact, the latter at some time acquired the entire tablet interests of Mr. Bower. Patents were also issued to Charles Killgore in 1882 and 1883,²⁵ and to J. T. and C. T. Jones in 1882.²⁶ From this time forward inventions in tablet machinery were numerous. The most familiar names in the industry are C. L. Jensen, F. S. Hereth, C. A. Tatum, E. C. Clark, Arthur Colton, E. V. Pechin, E. L. Richards, E. D. Dühring, J. F. Buckley, and A. M. Hance. A list of the patents for tablet machines consulted is given in the bibliography at the end of this paper.

FIG. 12—Remington pill press.

TABLET TRITURATES (MOLDED TABLETS), SOLUBLE TABLETS, AND TABLET SATURATES.

The homeopathic profession²⁷ had for years been using triturations and medications in the form of pellets, saturated with suitable medicinal agents. Efforts had been made from time to time to bring the several professions of medicine closer together on the subject of medication. In 1877 Dr. H. G. Piffard read a paper²⁸ before the New York Academy of Medicine on "The Use of Certain Triturations," in which he called attention to some of the advantages of triturations. He gave the homeopathic profession credit for their development, but did not think any one should enjoy a monopoly of their use. Some of the triturations mentioned he had "compressed into convenient doses." This article appears to represent Piffard's contribution on the subject of tablet triturations, but it clearly shows that he was the first to have recorded the fact that he had

²³ U. S. Pat. 215452, dated May 20, 1879, appln. filed Mar. 28, 1879.

²⁸ Med. Rec., 1877, 12: 756.

"compressed into convenient doses" triturations, and had brought them to the attention of the medical profession.

Dr. R. M. Fuller,²⁹ in speaking of Dr. Piffard's work, says:

"Dr. Piffard has found that a plate three millimetres in thickness, containing holes six millimetres in diameter, will produce tablets of about one decigramme in weight, while a plate four millimetres in thickness, with holes eight millimetres in diameter will produce tablets of about two decigrammes in weight."

FIG. 13—Killgore machine. Patented in 1883.

Dr. Robert M. Fuller is, however, undoubtedly the originator of tablet triturates and the moving spirit in placing the industry on a substantial basis.

In 1878 his first contribution, entitled "Dose Dispensing Simplified, an Easy, Economical, and Accurate Method of Dispensing Medicines in a Compact and Palatable Form," appeared.³⁰ In this paper he described "soluble tablets," "tablet triturates," and "tablet saturates." "Soluble tablets," as made by him, consisted simply of certain medicines made into a soluble paste with the aid of sugar of milk and alcohol or water, and molded into form. In some instances, however, he found it necessary to employ a more effective excipient than sugar of milk. His purpose was to prepare a tablet readily soluble or disintegrable

²⁹ Med. Rec., 1878, 13: 185.

³⁰ Med. Rec., N. Y., 1878, 13: 184.

FIG. 14—Robert M. Fuller.

"A Convenient Method of Dosage and Administration. The Process of making Tablets of Simple and Compound Powders, including Triturations, Hypodermics, etc."³¹ This contribution is an amplification of the work described four

in the mouth or in a spoonful of water. His "tablet triturates" consisted of triturations of metallic, mineral and vegetable matter, such as were discussed by Dr. Piffard in the paper referred to. These preparations were mixed into paste with alcohol or water, according to the adhesiveness required, and the paste molded into any size desired.

Tablet saturates are made by first molding sugar of milk into convenient form and saturating the blanks by immersing in the liquid to be used for medication, or dropping it upon them by means of a pipette. The term "tablet saturates" is now seldom used in practice. Dr. Fuller in the same article describes somewhat in detail the apparatus he used for the manufacture of soluble tablets, tablets triturates, and tablets saturates.

In 1882 the same investigator presented another paper before the New York Materia Medica Society, entitled

FIG. 15—Fuller's early mold.

³¹ Med. Rec., N. Y., 1882, 21: 311.

FIG. 16—Fuller's tablet saturate device.

years earlier. In it he gives another form of tablet mold, an illustration of which is given in Figure 17.

Dr. Fuller says in this article: "The idea of their adaptability for this purpose was the outgrowth of general laboratory practice in pharmacy and chemistry during 1861 to 1864. * * * * * The triturations were prepared in the manner elaborately and interestingly described in a text-book, used in connection with my earliest experiments, and entitled Mohr & Redwood's 'Practical Pharmacy,' and published in London in 1849. * * * * *" The method in question which assures the same accurate results as obtained by the process of compression, was the outcome of a long series of experiments made in this line

FIG. 17—Fuller's improved mold.

as early as 1861, before the system of compression was generally known or adopted in this country.

Dr. Fuller is fortunately still living and contributes the following letter, detailing briefly his early connection with the evolution of tablet triturates:

"Schenectady, N. Y., August 15, 1913.

"Dr. L. F. Kebler, Chief of Drug Division, Bureau of Chemistry,
Washington, D. C.:

"Dear Sir—Agreeable to your request of January 10th ult., and also further correspondence from Dr. Fraser and yourself, I am writing you a brief statement of my claim as the originator of the making of tablets in this country.

"Having received considerable printed matter from me and being familiar with the two papers prepared and read by me, the one under date of February 21, 1878, before the New York Academy of Medicine, and the other under date of February 23, 1882, before the Materia Medica Society, and also having at your command many articles and editorials with reference to my work along the line of the tablet industry, I feel sure that no detailed statement is necessary at this time.

"In the spring of 1861 I was employed in a drug store where I first began the practical work of making pills, subsequently called tablets. I subsequently took a full course in chemistry in the laboratory of Union College from 1861 to 1863.

"During all this time and for many years, I was greatly interested in the industry of making apparatus with which to find a convenient method of making compressed tablets and Tablet Triturates. At first, in 1861, the process for making porous pills was very simple and finally resulted in producing the 'Tablet Triturates' as now used as well as the compressed tablets.

"My work has been continued from that time—1861—with more or less interest, and while I am not inclined to be presumptuous, I might say that I was known as the 'Father of Tablet Triturates.'

"I was well acquainted with Dr. Piffard, but never knew that he made a claim as the discoverer of any tablet process. I well know that I first brought attention of the medical profession to the 'Tablet Triturates.' Dr. Piffard and I worked together long after I had invented the process. I have abundant proof among my private papers of the above facts but too much space would be required to go farther into details at present.

"Yours truly,

(Sgd) "ROBT. M. FULLER, M. D."

Numerous editorials and trade references are available to show Dr. Fuller's connection with the early evolution of this industry. The following editorial appears in "New Remedies"³²:

"Dr. Fuller's method of subdividing remedies (see page 69) so as to enable them to be administered in an agreeable form, and in uniform and adjustable strength, with the least expenditure of labor, appears to be a step in advance of previously-known pharmaceutical methods, and, like some other inventions of practical utility, surprises us by its simplicity, and makes us wonder why it was not suggested long ago. * * * *

"So far as we are able to judge from examination of Dr. Fuller's specimens, and from seeing his processes of manipulation, there is now little reason why they may not prove to be among the most successful of the methods yet proposed for the accurate subdivision of doses.

"Certain it is that Dr. Fuller is entitled to great credit for the persistency with which he has worked out the problem, and overcome its difficulties."

³² New Remedies, Vol. VII, 65, March, 1878.

In a circular published by Boericke & Tafel, April, 1878, appears the following:

"New Pharmaceutical Preparations, in Separate Doses, in a compact and palatable form. Soluble Tablets, Tablet Triturates, Pill and Tablet Saturates, made according to Dr. Robert M. Fuller's method as published in the Medical Record of March 9, 1878."

In a circular to the trade issued April 8, 1878, by Caswell, Hazard & Co., appears the following:

"Soluble Tablets, Tablet Triturates, Pill and Tablet Saturates, made according to Dr. Robert M. Fuller's method."

Fraser & Company, in a leaflet issued December 10, 1881, speak of "Tablet Triturates made according to method proposed by Dr. Robert M. Fuller."

The cut shown in Figure 18 was circularized to the trade in 1886.

A letter from Messrs. Boericke & Tafel, of Philadelphia, shows that the form of medication advocated by Dr. Fuller was put on the market soon after his contribution appeared in print. The letter is as follows:

"Philadelphia, January 7, 1913.

"Mr. L. F. Kebler, United States Dept. of Agriculture, Washington, D. C.:

"Dear Sir—We have endeavored to find some data in reference to the early history of the manufacture of tablets and find that we can give you very little information. We published from 1871 to 1885 a quarterly bulletin announcing anything new of interest to physicians in our school. In the May, 1878, issue we find an article on the use of certain triturations by Dr. Piffard taken from the December number of the Medical Record, which is no doubt the article you refer to. We find no mention made of the announcement of the manufacture of tablets until the August, 1879, number in which there is a statement made that we can now furnish tablet triturates giving prices, etc. The following statement was taken from the May, 1884, number:

"We have been subjected to some criticism for pushing these goods, and will take this opportunity to briefly state our position in the matter:

"In the December 1, 1877, number of the Medical Record, there appeared an article that had been read before the New York Academy of Medicine by Dr. Piffard, calling attention to the homeopathic triturations, and recommending the use of our first and second decimal triturations of a number of the active drugs, it being as-

serted that they were found to be more prompt and reliable than these same drugs when exhibited in the ordinary mode and form.

"In February, 1878, Dr. Robert M. Fuller read a paper before the same body, in which he referred to Dr. Piffard's address, and proposed as a convenient mode of dispensing these triturations, an invention of his, which he styled "Tablet Triturates," which consisted in forming of these triturations suitably sized tablets, each of which constituted a dose."

"The idea found much favor, and to supply the demand, we prepared a list

FIG. 18—Package of tablet triturates.

of our regulation triturations, of which any given trituration is made into tablets containing the usual dose of two grains.

"Later on,³³ tablets containing larger proportions of crude drugs were ordered by old-school physicians, and the trade assumed such proportions that we prepared the list, again published in this number, styling them 'Dosimetric Tablet Triturates,' in contradistinction to those of the regular homeopathic triturations.

"They are prepared according to Dr. Fuller's method with one difference, i. e., substituting glass plates for those of hard rubber, an obvious advantage, the increased cost of which has so far prevented others from following suit.

"Trusting that the above will help you in your investigations, we remain,

"Yours truly,

(Sgd) "BOERICKE & TAFEL."

Dr. Fuller is said to have laid the details of his investigation before Horatio N. Fraser, who at the time was in charge of the prescription department of a large New York pharmacy. It is also stated in literature that after a vain attempt to induce his employers to take up the industry, Fraser started the manufacture of molded tablets in a modest way in 1881. The records show that Caswell, Hazard & Co. were prepared to supply physicians with soluble tablets and tablet triturations, made according to the method of Dr. Fuller, as early as April 8, 1878. In a circular issued April 1, 1878, by Boericke and Tafel appears the following statement:

"Acting on Dr. Robert M. Fuller's valuable and eminently practical suggestions as set forth in his article above mentioned, we are engaged in getting ready a line of goods in conformity therewith * * *."

Dr. Fraser³⁴ in discussing these matters, says:

"I am glad you wrote me the letter about the circulars which seem contradictory, because it gives me a chance to say some things which I would not have bothered you with before, but which seem necessary under the circumstances.

* * * * *

"My fire, some years ago, destroyed all my papers and I had no copy of the circular, photograph of which you sent me, but I saw it in Dr. Fuller's office when I was in Schenectady and both recognize and remember it.

"While there I also saw a list of Wyeth & Bro. dated 1877, in which no mention was made of the word tablet that I could find. I also saw a Wyeth list which I think was dated 1883, and which spoke of tablets. This was the first Wyeth list I remember of seeing which did mention tablets.

"I notice that I mentioned Wyeth's *New Hypodermic* tablets in my circular of 1881—I suppose from this that they had put a hypodermic tablet on the market about that time but whether they called it 'Tablet' or not I do not know, but would infer as much from the language of my circular, though I may have had the word in my mind when writing the circular, and gave it the term, myself.

"I came to Caswell, Hazard & Co.'s store under the Fifth Avenue Hotel in 1876, from being a classmate of one of the Hazards in college. I worked there until just before the first of May, 1881, and during most of this period had charge of their prescription department, consequently was there during the time when tablets were introduced to the profession. I rented my first store May 1, 1881, and opened it about the last of July in the same year.

"I also recognize Caswell, Hazard & Co.'s circular. While I had been there continuously from 1876, I do not remember the date, but know it was about that time when they first made tablets. I cannot remember making any of them at

³³ Boericke & Tafel's Bulletin of Homeopathic News, May, 1884.

³⁴ Private letter to writer.

Caswell, Hazard & Co.'s store until just after Doctor Fuller's first paper was read, but W. F. Ford, who was head of the surgical instrument department of C. H. & Co., and another specialty manufacturer in the same factory building, must have been experimenting and working with the molds long before that, because they had them in shape to make fair tablets at the time the paper was published.

"W. F. Ford has been dead some years, but I have just had a conversation with Clarence Ford, his son, who worked in the C. H. & Co. surgical instrument department from 1875 to 1880. He says that, as well as he can remember, his father commenced to experiment with molds either in 1876 or 1877.

"Another indication that the date on the Caswell, Hazard circular is at least about right, is that Mr. Caswell of that firm had gone out of the concern a few months after I came with them. He started the firm of Caswell & Massey and was at that time in a dispute whether Caswell, Hazard & Co. had any right to that name, for the reason that he did not sell out his interest but took a *pro rata* amount of the stock and fixtures for his share.

"Caswell, Hazard & Co. lost the suit and changed their name to Hazard, Hazard & Co. after the decision of the court. I do not remember whether they were allowed to use the trade mark with the oldest name of the firm on (Hazard & Caswell) or not.

"My personal connection with tablets commenced, as I say in my letter of October 6, when I was a clerk in Caswell, Hazard & Co.'s (or Hazard, Hazard & Co.'s, as it was after the decision of the court), consequently my name should not figure in their history until I went into business with Mr. Fairchild in 1881.

"But having been most of the time from 1876 to 1881 at the head of Hazard, Hazard & Co.'s prescription department, I personally had something to do with their manufacture, because they made them in a very small way, as shown in your photograph of their circular dated 1878, the last paragraph of which says 'and will make special rates when 100 or upwards are ordered.'

"As well as I can recollect, it was just after Dr. Fuller read his paper on tablets that either Mr. Hazard or Dr. Fuller asked me to go up to the doctor's office on a special errand. While there he showed me what he had done and the details of the process that I might start making them at once for Caswell & Hazard Co.'s business. In the course of our conversation he said that he wished to have nothing to do with the trade end of the matter, and that he wanted to give the result of his work to the profession for their benefit without any returns or profit to him; and had made Mr. Hazard promise to have no secret about any of the formulas and to patent no part of the idea or processes. He also made me promise the same thing, and I, at least, have kept both the letter and spirit of that promise.

"At that time either he told me, or Mr. R. N. Hazard told me, that the doctor had talked to other firms about his idea but that none of them could see anything in the doctor's ideas, especially as they were complicated with his ethical restrictions.

"The Hazards made the tablets in a small way for some time and I could never induce them to go into their manufacture in what I thought was a business way.

"One of my principal reasons for leaving the Hazard employ was the idea that there was a future ahead for tablets, and my business was based on their manufacture and the idea that a druggist's success depended on what he did for and suggested to physicians.

* * * * *

"To sum up: I have no doubt but that Dr. Fuller should have the credit for precedence in the history of tablets; that either Caswell, Hazard & Co. or Boericke & Tafel made the first of them for the market, and all I had to do was the work of perfecting their manufacture, as was incumbent on me as the head of the prescription department of Caswell, Hazard & Co. at the time they

were introduced, and the faith I had in what they would do for the physician in the mechanical branch of medicine.

"I have done the best I know how to help you get at the history of Tablet Triturates."

As will readily be seen from the foregoing historical data, compressed tablets and tablet triturates, from which all other varieties originated, have had different lines of evolution. In point of time, however, the improvements proceeded almost simultaneously. Tablet triturates are either compressed³⁵ or molded. Their upper and lower surfaces are flat. In the case of compressed tablets the upper and lower surfaces may be either convex or flat. The three workers who stand out in the early history of the industry are Brockedon, Dunton and Fuller.

DEFINITIONS.

The term "tablet" has been applied to solid medicines of certain forms for several centuries. Samuel Johnson³⁶ gave the following definition for the term "tablet" and an illustration of its use:

"A medicine in a square form.

"It hath been anciently in use to wear tablets of arsenick, or preservatives, against the plague; as they draw the venom to them from the spirits.—Bacon."

The same definition will be found in the edition of 1819 and in the reprint of 1827.

M. Baumé³⁷ as early as 1762 devoted several pages (526-541) to the subject of "tablettes." He also gave a number of formulæ for preparing "tablettes," of which the following is representative:

Des tablettes altérantes, qui se font à la cuite du sucre.
Tablettes béchiques.

Sucre		lbj
Racines de Guimauve	} aa.....	3 iij
Réglisse		
Iris de Florence.....		3 j
Gomme adragant		3 ij
Opium préparé par digestion.....		gr. vj

The same author in the second edition of his book on "pharmacie" gave the following formula³⁸:

Tablettes antimoniales de Kunckel (lived 1630-1702).		
Amandes douces pelées.....		3 j
Cannelle		3 iij
Petit Cardamome		3 ss
Antimoine crud préparé.....		3 ss
Sucre		3 vij

Kunckel died in 1702 which clearly shows that tablets as then known were made previous to that time. The term "tablet" was applied to a mixture of melted camphor and white wax in 1847.³⁹ Chlorate of potash tablets were re-

³⁵ So far as records show, Dr. Piffard was the first to have recorded the manufacture of compressed tablet triturates.

³⁶ A Dictionary of the English Language, 1st ed., 1755.

³⁷ Elemens de Pharmacie, 1762, 1st ed.

³⁸ Elemens de Pharmacie, 1769, 2d ed., p. 707.

³⁹ Pharm. J., 1847, 7: 47.

ferred to in the same journal as early as 1862.⁴⁰ Burroughs, Wellcome & Co. wrote as follows⁴¹:

"We registered the word "Tablets" in this connection as a trade-mark, and therefore regard it as our rightful property, also because we introduced the word here, and because it is in our opinion non-descriptive, and therefore eligible for use as a trade-mark. We still employ it on some of our goods. A 'Tablet' has never been described or considered as a substance having a round or oval surface, but rather as having a flat or squared surface. In the compressed form of medication the surface is rounded or curved. Some firms have, we presume, inadvertently used the word 'Tablets' in connection with compressed drugs."

According to the "British Trade Marks Journal" of February 28, 1883, page 115, a trade-mark, No. 31,235, was issued to this firm, but apparently not solely on the word "tablets." The trade mark is in the form of a rectangular figure with the word "tablets" impressed upon it. This is quite a different matter from claiming the exclusive right to the use of the word "tablets." Additional information upon this subject will be found in the "Chemist and Druggist."⁴²

The name "tablets" is sometimes restricted to tablet triturates,⁴³ but trade practice does not warrant such limitation. At present the designation "tablets" is a general term and cannot be said to mean any special kind of tablet.

Every indication tends to show that the term "compressed tablets" had its origin in the United States and that John Wyeth and Brother were the originators of the name.⁴⁴ Registered trade-marks No. 1001 and 1002 were issued to that firm on March 13, 1877, covering the term. The copy of a label found in the U. S. patent office records of one of the above numbered marks follows:

"Compressed Tablets of Chlorate of Potash for Hoarseness, Bronchial Irritations, Sore Throat, Ulcerations, Mercurial Salivation, Diphtheria, Croup, etc., etc.

"FOR SORE THROAT, HOARSENESS.

"Directions:—Adults should take one every hour or two until relieved, allowing it to dissolve slowly in the mouth. Children half of one as often.

"For offensive breath, no remedy will give more certain relief. Use one, two or three times a day.

"For diphtheria, croup and the more serious ailments, the physician should direct.

"JOHN WYETH AND BROTHER, PHILADELPHIA."

Dispensary tablets. A soluble form of medication of accurate composition, for the use of the pharmacist in preparing certain solutions, thus dispensing with the necessity of weighing.

Dosimetric tablets. A form of tablet triturates prepared to give accurate dosage used as early as 1884.

Hypodermic tablets. These are soluble tablets for hypodermic use for both human and veterinary purposes.

Molded tablets. This term covers any form of medication prepared in molds of the kind first brought forward by Dr. Fuller. The two sides are usually flat.

⁴⁰ Pharm. J., 1862, 22: 40.

⁴¹ Chem. and Drug., 1892, 40: 785.

⁴² Chem. and Drug., 1890, 37: 531, 563, 603, 665, 695; 1892; 40: 785, 817, 849, 881.

⁴³ Remington, Practice of Pharmacy, 1907, 1199.

⁴⁴ Chem. and Drug., 1883, 25: 567.

It should be stated, however, that not all tablets with two flat surfaces, "block tablets," are molded.

Ophthalmic tablets are tablets containing medicinal agents for the use of oculists, and the filling of their prescriptions by druggists.

Proprietary tablets. This term is applied to proprietaries in tablet form.

Soluble tablets. A general designation applied to all forms of tablets soluble in water.

Tablet saturates. A form of medication introduced by Dr. Fuller but at present little used, as is shown by the following letter:

"Philadelphia, February 13, 1913.

"Mr. L. F. Kebler, United States Dept. of Agriculture, Washington, D. C.:

"Dear Sir—In reference to the use of tablet saturates would state that these are not much used by doctors. Our dilution and tincture tablets, of course, are practically tablet saturates only that the tincture and dilution are mixed in proper proportion with sugar of milk and then molded into tablets, whereas the tablet saturates are made by taking the blank sugar of milk tablets and merely saturating them with the tincture or dilution. The former, you will see, is a much more accurate preparation, as the exact amount of liquid can be added to the sugar of milk so that each tablet will contain a specified amount.

"Very truly yours,

(Sgd) "BOERICKE & TAFEL."

Tablet triturates. A term originally applied by Dr. Fuller to molded tablets. At present, however, it is indiscriminately applied to all tablets, soluble or insoluble, having two flat surfaces. They may be made by either molding or compression.

Veterinary tablets. This is a term applied to tablets used in veterinary practice.

MANUFACTURE.

INGREDIENTS.

Experience had shown in the time of Brockedon that pills as then made with adhesives often operated to the detriment of the patient. They became hard and indisintegrable for practical purposes. Brockedon conceived the idea of compressing drugs without the use of adhesives, thus eliminating this undesirable feature. So far as the records show he compressed soluble chemicals only, and his best known tablet was "soda and potash." "Chlorate of potash" tablets were best known and made in the United States. How long the practice of compressing soluble chemicals without adhesives prevailed is not known, but there is reason to believe that these adhesives began to be used in the early seventies. It is definitely known that Dr. Fuller used them in preparing tablets proposed by him in 1878.

Tablet triturates appear to have been specially devised for molding insoluble drugs into tablet form, and there are reasons for believing that Dunton did this long before, because he had acquired a reputation at this time for his "quinine tablets," as they were then known. There was no trouble in making tablet triturates as usually understood, but the compression of insoluble agents without adhesives presented numerous difficulties. Without these agents it was necessary to use undue pressure, thus making an extremely hard tablet, which might,

and even did, pass through the system intact, would be void of medicinal action, and might jeopardize the safety of the patient. Difficulties also arose because the tablets adhered to the various parts of the compressor. Dunton, in his process patent, provided for several forms of lubrication. The ideas he advanced are fundamental and are still basic in the industry. It is reported that the secret of Dunton's success in producing "pure tablets" without the use of adhesives or foreign material was due to the fact that he made each alternate tablet of chalk, which must be looked upon as a process of lubrication, or cleaning out the mold preparatory to another operation.

The situation in the early eighties was, therefore, that the compressed tablet industry would be restricted to the manufacture of tablets from chemicals soluble in water, which placed the industry in a very awkward position in view of the fact that tablet triturates, and soluble tablets, as molded by Dr. Fuller, were not confronted with this obstacle. The desideratum was now to prepare tablets containing insoluble ingredients which would readily disintegrate in the system in order to obtain medicinal effects. An agent was needed which would break up the tablets when moistened or placed in water. It is reported that numerous investigations were made and discoveries claimed, but nothing appears in the records. If anything was discovered and used it was kept a trade secret until 1887, when Charles Killgore applied for a patent. Mr. Killgore relates the circumstances leading up to the discovery as follows:

"In the spring of 1887 Mr. Fraser called upon me and stated that he had received complaints that the acetanilid combinations did not disintegrate readily when placed in water and I told him that I would make experiments and see if the objection could not be overcome. The criticism of Mr. Fraser recalled to me an experience I had in trying to make bi-carbonate of soda tablets in 1881. In order to get a nice, smooth tablet I had added enough potato starch to the soda to keep the tablet from sticking to the dies and by so doing obtained a beautiful looking tablet and of course thought my troubles were over, but, on examining them the next day I found they went to powder on being touched. They had been near a sink in the back room and absorbed enough moisture to swell the fecula of the starch and you might as well have tried to pick up a soap bubble. Based on this experience I then made a series of experiments with acetanilid combinations and found that starch in proper quantities would accomplish the disintegration of the tablets when they came into contact with moisture, and further experiments demonstrated that it would work with a large percentage of tablets that were used. In May, 1887, I filed an application for a process patent covering the addition of starch to dried materials before being compressed, for the purpose of disintegrating them in the presence of moisture. The application was rejected on the ground that starch was used in so many products. Up to this time it had not been used in compressed tablets, but since then has come into general use, as I made no secret of it."⁴⁵

Mr. Kilgore's application, No. 238,375, which was filed May 16, 1887, is in part as follows:

"It is well known that the administration of medicines in the form of compressed tablets or pills, while having many advantages, has been open to disadvantage arising from the slowness with which the same dissolve in the stomach.

"The object of my present invention is to form compressed tablets or pills which, while possessing all of the advantages of those heretofore employed, are

⁴⁵ Private communication.

not attended by the disadvantage above referred to; in that when subjected to moisture they rapidly disintegrate. This result I accomplish by mixing with the ordinary ingredients constituting a compressed tablet or pill a percentage of starch which will so change the character of the compressed tablet or pill that the same will not be open to the objections heretofore existing.

* * * * *

"In making my improved compressed tablet or pill the same is prepared in the usual manner down to the point where the preparation is ready to be submitted to the action of the pressing machine. At this point I mix with the other ingredients a percentage of starch; and having done so, the mixture is subjected to the same operations as were heretofore employed for completion of the tablet or pill.

"Since the application of my improvement is not limited to tablets or pills of any particular constituents but may be generally applied, the percentage of starch to be preferably employed will vary in different cases. Some kinds of tablets or pills require a larger percentage of starch for obtaining the desired object than others. It will be sufficient for me to mention as an example, that in making compressed tablets or pills from bismuth, it will be found desirable to add about five percent of the starch. The starch being a substance which has substantially no injurious influences, of course an excess of it is not harmful.

"The tablet or pill resulting from my invention possesses, as far as I know, all of the qualities of those heretofore made excepting that when taken into the stomach it immediately disintegrates.

"I claim a compressed tablet or pill containing a substantial percentage of starch, for the purpose of facilitating disintegration, as set forth.

(Sgd) "CHARLES KILLGORE."

The rejection of the application is given in the following notation of the Patent Examiner on the application:

"The claim would not be patentable aside from novelty in view of the dec., Tarr vs. Webb, 2 O. G., 568.

"Starch is the most commonly used dividing agent. It enters into pills, tooth-powders, baking powders, and toilet powders generally. See Griffith's Formulary, p. 516, Br. Pat. No. 1630 of 1857, and Tooth and Baking Powders in the various Encyclopædias. Such having been compressed, there is neither novelty nor invention in applicant's procedure. See also Br. No. 202 of 1870. The application is rejected."

The reasons for disallowing the patent were general and, it must be said, not very convincing. The phenomenon observed was new and its application was undoubtedly novel. The discovery was a great triumph for the industry. From this time forward its growth was simply phenomenal. All conceivable solid drugs are now compressed into tablet form, and some fluids are also incorporated, often, however, with unsatisfactory results.

It seems hardly necessary to consider even briefly the various medicinal agents compressed. They may be found in simple or composite form in the general trade price-lists. It is, however, desirable to state somewhat in detail the excipients or adjuncts used in compressing them.

EXCIPIENTS.

The term excipient is applied to any substance other than the medicament used in the manufacture of, or which enters into the composition of, tablets or pills.

Excipients may, for convenience, be divided as follows: Liquids, adhesives, bases, disintegrators, absorbents, lubricants, and fillers.

LIQUIDS.

The liquids used consist essentially of water, ethyl and methyl alcohol, as well as mixtures of benzine and either of the alcohols. Their purpose is to facilitate granulation and to dissolve a small portion of the adhesive, thus increasing the adhesion or cohesion of the particles.

ADHESIVES.

These consist of cane sugar, milk sugar, acacia, tragacanth, glucose, gelatine, Irish moss, and dextrin. Cane and milk sugars are the most valuable and most commonly used. When they are properly employed no additional adhesive is necessary in many cases. Cane sugar is preferred by some on account of its greater solubility, while others prefer milk sugar because it makes a more porous and absorbent tablet. Cane sugar is used in the form of both powder and syrup. Acacia is employed in powder and mucilage form. The latter is more effective than the powder subsequently moistened. This adhesive must not be too freely used on account of its tendency to produce "insoluble tablets," or those which disintegrate with difficulty in the system. Tragacanth is seldom used except in cases where it is difficult or impossible to prepare sufficiently firm granulations by other means. Glucose, gelatine, dextrin, and flour are used only for certain mixtures. Gelatine in tablets is liable to become moldy, thus rendering the tablets unfit for use. Some, however, say that this criticism is unwarranted.

(To be continued.)

THE NEW AGE.

This is an age of social service. Never in all history has the world been so concerned in the welfare of "the other half"; never has there been such a strict inquiry into the life conditions of all peoples; and never has there been such concerted action to relieve suffering and social wrongs, as we see manifested so generally to-day. Surely the "millennium" is at hand. Well may we say with Riley:

"This world is a curious compound, with its honey and its gall,
With its tears and bitter crosses, but 'tis a good world after all.
And a good God must have made it—leastwise that is what I say,
When a hand is on your shoulder in a friendly sort o' way."

Everywhere the hand of social service is being laid upon the shoulder of the poor and unfortunate, the oppressed and the needy "in a friendly sort o' way." It is a great work and is enlisting the co-operation of all classes of people. The layman in his sphere, and the members of all professions are working side by side—each in his sphere—to bring about proper life conditions for all.—*Russell W. Bunting, D. D. S., in Lehn & Fink's Dentist's Diary.*

Contributed and Selected

NATIVE DENTISTS IN CHINA.

J. F. RUPERT, U. S. NAVY, HOSPITAL CORPS.

Now that China is awakening from her long slumber of seclusion and self-satisfaction, in line with her progress in other directions, many evidences of an intelligent interest in modern dentistry may be observed in the Celestial Empire. In the large port-cities, many Chinese of the better class will be seen to have visited up-to-date dental establishments by evidences of modern dental work which they display. This has been done usually by foreigners practicing in China, and in some instances has been performed abroad; but in other cases—a direct evidence of progress—very satisfactory dental work is performed by native practitioners who have been educated abroad or who have been instructed in China under the eye and direction of the men who have learned their profession in foreign lands.

While this modern dental work is the fruit of the late progressive movement in China, the native element of self-sufficiency still prevails for the greater part with the masses, and the native dentist, pursuing his practice along the same lines his ancestors have followed for centuries, still conducts his business perhaps on the very spot where his father practiced the same profession.

Throughout China, on street corners and in alleyways, the native dentist may be seen, exhibiting hundreds of incisors and molars, as evidence of his skill and as encouragement to others to add their bit of ivory to the stock already on hand, which collection probably comprises many inheritances from former generations.

His furniture consists of a table and chair. His instruments consist of the crudest forceps and scrapers made to order at the blacksmith shop. Of medicines he knows nothing. His real stock in trade are his wits and his general power of argumentation.

Silver fillings are made, but no gold work is attempted. He has no drills and the cavity is scraped out with home-made spoons. The technique of his work consists of filing silver coins and mixing these filings with mercury, which amalgam, after being inserted into the cavity, rapidly hardens; but trouble often arises later when as is likely the more or less exposed nerve resents such primitive treatment and the pseudo-dentist is at a loss for means of removing the filling. Nothing can then be done by him but extract the tooth.

The price charged for extraction of teeth is from 20 to 40 cents, local currency (about 8 to 16 cents gold), for each. Price is arranged to meet the financial standing of each individual; while earnest endeavor is made to convince the patient that *his* particular tooth is most difficult to extract and requires exceptional skill—all of which adds increased expense.

As in all dentistry practice, the Chinese practitioner will occasionally encounter cases which he would rather have had presented to the "man across the street," but the Mongolian practitioner thinks as much of his professional reputation as his more civilized *confreres*, and when such cases present themselves his wits are equal to the occasion. He dismisses the patient by stating that the tooth is a "blood tooth," and should it be extracted the patient will most surely bleed to death. This explanation should be sufficient for any one, white or yellow, but pain is not easily disposed of and in cases where the extraction of the tooth is insisted upon, the dentist will explain that as his assumption of the responsibility of extracting the tooth carries with it possibilities of grave results to his career and reputation, he cannot attempt the operation for less than \$5.00. This is expected to cause the patient to seek relief at a less price, and this is the usual result.

I have seen these street-corner dentists extract teeth by fastening a strong thread about the tooth and extracting it by leverage.

However, as in the practice of medicine, so in the practice of dentistry, we find many very good Chinese practitioners who use modern methods. In Nanking, at one time the Imperial capital of China and a city with an old and important history, showing evidence of the present progress in China along these lines, a young Chinaman has established a very fine dental parlor. A large waiting room for foreigners, with the latest magazines of America and Europe upon the table, and separate rooms for Chinese patients have been provided.

This man, Dr. Yin Seong Hoh, was taught his profession by an American dentist in Honolulu. He has a complete equipment, a strictly up-to-date and well-selected dental library, and his methods and practices are in accordances with modern ideas on asepsis and antisepsis. Nanking has not more than eighty foreign residents, mostly missionary people, and this energetic young man is building up a good practice among the Chinese who have learned about some of the benefits of European civilization. Shanghai has a Chinese dental firm, Kingman & Kingman, who have a large and well-equipped establishment. The wealthy Chinese are patronizing this work, and eventually it is bound to spread to the common people, for it is not from lack of confidence in such work that it is not more general, for crude dentistry has been practiced for centuries in China, but the price charged looks extravagant to people whose one ambition in life is to make money. A rich native of the great yellow empire spends money with prodigality, but he prefers, like most of us, to spend it in other ways than patronizing his dental brothers.

SPECIFICATION IN BUYING DRUGS.*

C. R. NOYES.

The interest and value of scientific work in pharmacy lies largely in its everyday application. I believe you gentlemen are more interested in hearing of the final results of experimental and research work as it applies to you and your daily business, than you are in the theoretical and purely scientific description of method, apparatus, etc. Following out this idea, I am going to give you the conclusions drawn from a very large amount of analytical data on the raw materials of the market. These conclusions naturally take the form of suggestions to you as to the specifications for the raw materials which you buy. In other words, I am going to try to suggest to you certain definite specifications which are good to use in buying your drugs, and through which you can take advantage of this scientific examination of market chemicals and drugs that has been done during the last six years.

From the wholesale druggist's standpoint there are two conflicting interests at work in the selection of the raw materials for sale. He is probably desirous of giving as good an article as possible and he is certainly influenced by the desire not to supply anything which does not comply with the stringent drug laws. On the other hand, he must meet competition. He must buy an article which he can sell at a profit, in competition with the articles put out by his competitors. He tries to talk "quality," but always fears that his customers believe he is trying simply to get a larger profit and that he is not giving them better goods for their money. The result of this is, that the average wholesaler is convinced that some druggists do not care for "quality" but simply wish the cheapest article they can buy. If, therefore, he is compelled, by either a real or fancied demand on the part of the retailers, to sell the cheapest grades of drugs, he is not willing to state frankly upon the label or in his catalogs the exact quality of these goods. If he were to do so, his cheaper grade would immediately, in the eyes of the purchaser, seem to be inferior to the competitive grade offered by some other house, which was not definitely classified by statements of its label. The result of this condition has been that the wholesale drug trade, on the whole, is endeavoring to market low-priced goods, and is glossing over, as much as possible, the inferiority of the goods. Gentlemen, the only cure for this condition lies with the retail druggist. If you will specify definitely what you want and insist upon having goods definitely labeled as to quality, you will get good drugs at reasonable prices, for you will force your jobbers to meet each other's prices on a common ground, instead of trying to beat each other's prices on an inferior ground. Therefore, I believe that this matter should be brought to your attention and I hope the facts which I shall give you hereafter, which facts are based on the analytical reports of thousands of samples, will lead you to realize the true situation and to remedy it by specifying your exact wants when ordering goods.

The principal conclusion which I have derived from this work, is that the best

*Read before the Northwestern Branch & Minn. State Pharm. Assoc., Feb. 19, 1914.

and safest course for the retail druggist is to specify "U. S. P." on every article included in that standard of authority, the Pharmacopœia.

First, let us see how that suggestion affects the buying of chemicals. A wholesale druggist's stock usually contains two grades of each common chemical. The commercial, or ordinary grade, he buys and sells in bulk, while the so-called "C. P." grade is bought and sold in original packages, under the label of the manufacturing chemist. You will not find "U. S. P." specified very generally on chemicals. Now the commercial grade is, to the average wholesale druggist, of unknown quality. He has been handling Epsom salts, cream of tartar, permanganate of potash, etc., in barrels and drums, for many years without considering anything but price in purchasing, and he probably knows little or nothing of their purity. Doubtless he is buying from some large producer, the most of whose product goes for technical purposes, and who may have heard of the United State Pharmacopœia, but probably pays it little regard. These drugs, being sold to the wholesaler under labels as above, are consequently sold by him under the same label. Occasionally, to be on the safe side, he may put the words, "for technical use only" or, "commercial" under the principal title, but usually, he sells the goods under the same label he finds the manufacturer using. While the wholesaler is almost entirely at fault in this matter, nevertheless it may be said that many articles bearing the label "for technical use only" are accepted by druggists without hesitation. At the other extreme from these commercial grades, you have the so-called chemically pure articles. Of course they are not chemically pure. No chemical, not even those of reagent quality, can be. But, at any rate, they are highly purified. Of "highest purity" is the proper designation. This is the ordinary selection which you may make in buying chemicals from the stock of a wholesale druggist. It is a case of "out of the frying pan into the fire." You either take chances on a poor quality or pay excessive prices for the best quality. I am not sure which is "the fire." Often, the guaranteed purity and the beauty of the so-called C. P. chemicals, do not warrant the price asked for them, and, in practice, their super-excellence is often not demanded and is wasteful. Frequently, too, by being adjusted to a different standard, they vary from U. S. P. chemicals in strength, so considerably, that they must be standardized, before using in a U. S. P. formula. This is shown by the variations in strength between the C. P. and the U. S. P. mineral acids. Is it possible, you ask, to get out of "the frying fan" without getting into "the fire?" I think it is. If you specify U. S. P. *always and only*, your difficulty will be solved. The Pharmacopœia is a thoroughly practical, as well as a scientific volume. Drugs meeting the requirements of the Pharmacopœia are, in almost every case, just good enough for medicinal purposes. What need is there of having them purer? You will be surprised to find that you will frequently pay no more for U. S. P. chemicals, guaranteed to you, than for the present bulk goods, the quality of which is unknown to you. On the whole, the Pharmacopœia committee has directed standards for purity that are not expensive to comply with. There is one consideration, however, that you must learn to overlook if you buy U. S. P. chemicals and consider prices. If you secure goods labeled with these initials, from a house that you know has graded them from their own examination you must disregard their appearance. A large part of the expense of pre-

paring C. P. articles, comes from the many re-crystallizations, re-distillations, etc., necessary to secure their fine appearance, which is so much admired. If you do not wish to pay the price, you must be satisfied with the frequently mediocre appearance of the U. S. P. articles.

As applied to chemicals, then, insist on those marked U. S. P. and refuse all goods labeled with such vague specifications as, "pure," "purified," "white," "medicinal," "redistilled," etc. These same remarks also apply to the drugs and oils that are found in the Pharmacopœia, although, in the case of these drugs you will less often find a pure grade in the average wholesaler's stock, and you will also find fewer retailers who desire to pay the price for the U. S. P. grade. I think, if you consulted the employes of the drug-department of any wholesale druggist you would find that, in nine cases out of ten, their instructions were to send the ordinary commercial or technical grade of oils and drugs, unless a better grade was specified. And this is the result of experience and not from choice. It is because the retailer has too often returned the better and higher priced article, when it was sent him without his specific instructions.

Now I propose to give you some definite examples of the difference between the U. S. P. grade of a number of articles and the ordinary grade:

Castile Soap. Very little of the castile soap you buy is made from olive oil, or wholly from olive oil. It is manufactured from a compound of olive oil and tallow, in varying proportions. The proportions you know nothing about. It may contain a large quantity of water or a small quantity of water. In other words, you may be paying "Castile Soap" prices for water and for tallow soap—unless you order "Soap, U. S. P." If you do, the chances are good that you will get a pure olive oil soap, containing not over 36 percent water, which is the normal and maximum amount.

Lime. If you buy lime for making lime water, you will get an article containing perhaps 50 percent magnesia and also probably quantities of iron and other impurities. These impurities are, to a certain extent, soluble in water along with the lime, and you cannot possibly have pure lime water, if you make it of such an article. Specify "Calcium Oxide, U. S. P.," and you will get a product of at least 90 percent purity.

Precipitated Sulphur. The commercial grade of this article is called "Lac Sulphur." The U. S. P. article is prepared with hydrochloric acid. In the manufacture of the cheaper article sulphuric acid is substituted. The result is that the precipitate contains a large proportion of calcium sulphate which is inert. Now, however, the manufacturers have taken a step further and "Lac Sulphur," as it appears on the market, is derived from the surface sulphur beds without purification. It is not precipitated but shoveled, and does not contain more than 40 percent or 50 percent of sulphur. The balance is clay. Why buy clay?

Alcohol. Commercial alcohol, as it is ordinarily sold, is 94 percent. It is to a certain degree impure. "U. S. P. Alcohol," costing but a few cents more, is the old cologne or deodorized spirits, and contains 95 percent alcohol. It is hardly at all more expensive if you consider the increased strength.

Turpentine. I doubt if many druggists, even the gentlemen who come here,

are aware that the United States Pharmacopœia requires that Rectified Oil of Turpentine should always be dispensed for internal purposes. The term "Rectified" is such a loose one that if "U. S. P." is not appended thereto, you may not know that this re-distillation has included the shaking out with soda, an expensive process which causes a loss and is likely to be omitted if possible. Thanks to your pure paint laws, the ordinary oil of turpentine is quite safe. You are notified on the package if you get anything that is not "U. S. P."

Tannic Acid. This article is almost never "U. S. P." and it may contain any amount of impurities. In this case, I believe the standard, in regard to the amount of resinous matter present, is too stringent and should be modified. If you insist on having a statement on the label as to how much resin is present, you can probably secure for yourself as definite a value without specifying "U. S. P.," and at the same time save a little on the cost.

Oil of Eucalyptus. As ordinarily sold, it is the Oil of Eucalyptus Amygdalina. This contains very little eucalyptol and is comparatively valueless. "U. S. P." is the specification that will get you your money's worth in this case.

Oil of Gaultheria. Frankly, I do not recommend the purchase of this oil nor that of Sweet Birch. Use methyl salicylate. I have personally experimented with the methods of analysis used by several houses of excellent reputation, who claim to put out the true oil of wintergreen, and I am convinced that they are deceiving themselves, when they believe that they are able to differentiate these products by chemical means. The feeling against the artificial oil is largely due—first, to the fact that it is artificial, and second, to the fact that, when first introduced, there were present considerable impurities of a phenolic nature due to imperfect manufacture. With the perfection of the processes of manufacture, the cause for this prejudice has been removed, and methyl salicylate should now be recognized to be equal if not superior to the natural oils.

Glycerin. On account of the fact that much the largest part of the glycerin-production goes to the making of nitro-glycerin, much of the product on the market is not "U. S. P." The two common impurities in glycerin are butyric acid and acrolein, the one very distasteful and the other very injurious. Be sure that you find "U. S. P." on the package, and do not depend on some favorite manufacturer's name, which you have been used to seeing since the days when glycerin was a by-product of candle manufacture.

Talcum. This is called French chalk. It is, of course, not chalk, and has not the slightest chemical relation to chalk. Nevertheless as sold it usually contains large amounts of calcium and magnesium carbonates, lime, etc. We have found as high as 50 percent of these impurities. Unless your talcum is going to be used for filtration purposes, you do not need the "Purified Talcum of the U. S. P.," but for any purpose it is desirable to avoid an excessive quantity of lime, chalk and magnesium carbonate. The way to avoid it is to specify "U. S. P."

Rosin. Are you aware that rosin or colophony is also in the Pharmacopœia? Rosin is so cheap that there is not anything cheap enough to adulterate it with, when you buy it whole. But if you buy the powder, look out. On account of its low melting point it is very difficult to prevent rosin from forming lumps again after it has been powdered. The result is that the powdered rosin on the market

usually contains from 25 percent to 50 percent of a filler, bran, flour, etc., put in, not to adulterate it, but to overcome the difficulty of manufacture. On the other hand, when you are ordering rosin, you doubtless do not want bran, and I would suggest that you see that the label on your goods tells you what you are getting.

Aloes. The same situation is found in the case of aloes. This frequently contains varying proportions of pea-meal, etc., when sold in powdered form. Now the Barbadoes aloes and the Socotrine are official in the Pharmacopœia. But Cape aloes is not, and therefore the average grade of Cape aloes is very poor, as it has no standard to measure up to. Why not require a statement, upon your purchases of Cape aloes, of the percentage soluble in boiling water? When you buy powdered aloes you have the possibility of getting insoluble matter, in the form of pea-meal, as well as in the form of dirt and impurities present on account of careless collection. Probably it would be interesting for you to know what the insoluble portion consisted of.

Asafoetida and Benzoin. With these you pay for the amount of alcohol-soluble matter present. The Pharmacopœia requires 50 percent of the asafoetida to be soluble, and that the benzoin should be almost wholly soluble. Of course, a large part of both of these articles, as they appear on the market, do not comply with these requirements and probably this does no harm provided you insist on knowing exactly what percentage of soluble gum resin you get.

Anise Oil and Cassia Oil, as they appear on the market, are largely the product of Chinese stills invented during the period when the Chinese were discovering gun powder and printing presses, and they have not been improved since. They are very crude articles and are exported in lead-lined, copper containers from which they absorb a considerable quantity of lead and copper. Almost all of the oil of cassia and a great deal of the oil of anise sold to the drug trade are these technical articles which contain at least one poisonous impurity. The pure oil may be procured for a not much higher price, but it will never be supplied unless its purity is insisted upon.

Oil of Juniper and Oil of Lavender. These are two oils which are official in the U. S. Pharmacopœia, but which are principally sold in the form of "imitations." By "imitations" is meant simply this: You take so much oil of juniper or oil of lavender and you add to it so much oil of turpentine or other cheap pine-distillate. You adjust the proportions so that the cost suits you, adding a little something for the labor of mixing. Then you sell it as "Oil of ———, Imitation," at low price, and many people prefer it to the real thing.

Beeswax. You can have beeswax or beeswax-compound. You usually have a beeswax-compound. This is another joke of the wholesale drug trade. Beeswax-compound contains anywhere from 2 percent to 70 percent paraffin wax, according to the sense of humor of the manufacturer. I must say that, in this case, the manufacturer is usually not the wholesale druggist, and, personally, I sympathize with the wholesale druggist who has to buy and sell what is wanted. Sometimes, this beeswax-compound is sold as country wax or cup wax. If you want to pay someone for melting up beeswax and mixing it with paraffin, I suggest that you insist on knowing how much paraffin they use, because the competi-

tion in this article will doubtless eventually produce a pure paraffin-wax colored to imitate beeswax, and sold as beeswax-compound, unless something is done to stop it.

Linseed is another thing which is usually given but very little thought. It depends for its value wholly upon the presence of linseed oil and yet ground flaxseed, or linseed meal of the market, is very frequently a product which has been partly reduced to the condition of ground oil cake. In other words, the oil has been partly removed from it. The name "U. S. P." prevents that.

There are a number of articles which do not properly come within the scope of this paper, because they are not in the U. S. Pharmacopœia, and yet I am persuaded to tell you what they are, because I seem to have been exposing some fakes and I might as well make a clean job of it.

Do you every buy crude carbolic acid? If you do, DON'T. Or, if you must, buy it on a percentage basis. It varies on the market from 95 percent to 10 percent of phenol. Sometimes it has no phenol in it at all. This is the case when you are supplied with the so-called domestic creosote oil, which is often nothing but gas-house residues.

Coal-Tar Creosote is another little joke originated by the chemical houses, but no longer fathered by them. In fact, the leading houses have refused to supply this article. Coal-tar creosote, used as a substitute for beechwood creosote, is a solution of phenol in water of any strength that the maker happens to decide upon. Any merits which this article may have, that the regular solutions of carbolic acid have not, are due to psychotherapy.

Almond Meal Compound may contain any percentage of starch, flour, etc., that the manufacturer prefers, or it may be made entirely from these articles and flavored with oil of bitter almonds. If you want almond meal made from almonds and not from peach kernels, which is just as good, I would suggest that you require a definite statement of what you are getting.

Horse Medley is coal dust. It is sold for black antimony but it never saw a piece of antimony. It is remarkable that the same marvelous medicinal property of sleeking a horse's coat should be produced by two such dissimilar articles as antimony and coal dust.

Calamine. According to authorities this is an impure zinc carbonate, depending perhaps for its medicinal effects upon its impurities, which offer an opportunity for the imagination to enter into the results that you get from it. A great deal of imagination, however, is required. "Calamine, a compound," is what you usually get. This article consists of powdered sand colored pink, either artificially, or by impurities. This must be a most efficient remedial preparation! Silica is, about, the most fixed chemical known. You will remember that it is only affected by roasting with alkalis, and the only acid that will affect it is hydrofluoric.

When you know this, you will naturally refuse to take such an article and will buy the so-called "Calamine, pure precipitated," which is on the market under the labels of the well-known chemical houses. This preparation is doubtless a little joke on the mineralogists. It so happens that, in the classification of minerals, the name of calamine has been applied in Europe, to an impure zinc

carbonate. By all of the American authorities, however, it is applied to a zinc silicate. So, when the American houses wish to put out a calamine that is beyond reproach, they follow the American mineralogists. Powdered zinc silicate is almost as inert as silica. I believe if you are willing to forego the mysterious properties of the impurities of the old calamine, you will do better by buying and selling zinc carbonate, U. S. P.

Probably I have been a little severe on some of these products and on those who place them on the market, but that has not been my purpose. Your wholesale druggist will give you what you ask for. The remedy for this situation rests with you, and not with the wholesaler. No blame attaches to you, for you have not been in a position to know what you were getting. But, you will find your wholesaler most willing to coöperate in giving you a good raw material, if you but say the word and keep right on saying the word. The word is "U. S. P."

BIBLICAL REFERENCES TO PHYSICIANS.

According to a writer in the *Chemist and Druggist*, biblical reference to the physician and his work are not particularly numerous, neither are they particularly flattering. In Genesis physicians are referred to only as "embalmers," a title too suggestive of undertaking to be agreeable; Job has a reference to "physicians of no value," by which he probably referred to the "irregulars" of his day; three of the texts are versions of the saying about them that are whole and need not the physician; two refer to the woman who had "suffered many things of many physicians," which Luke (himself a physician) softens to "had spent all her living on physicians." Luke, by the way, is the only Evangelist who quotes the proverb, "Physician heal thyself." This Evangelist figures in the only really complimentary text, "Luke, the beloved physician"; and there is even here nothing to show that it was his profession that made him beloved. It was Dean Swift, who preaching before the Royal College of Physicians, took for his text, 2 Chron., xvi, 12-13: "Yet in his disease he sought not to the Lord, but to the physicians. And Asa slept with his fathers," which decidedly suggests the connection of cause and effect.

Papers Presented to Local Branches

THE PRODUCTION AND CARE OF ANTITOXINS AND VACCINES.*

J. REVERDY STEWART, M. D.

I have been asked by the President of your Association to read a paper this evening on the production of antitoxins and vaccines, and I have tried to arrange my remarks in order to have them of interest to the pharmacist.

The enormous progress that has been made in the past twenty years, and indeed I might say in the past five years, has brought so many new angles in the treatment of disease, that it well behooves the pharmacist of today to keep in touch with the production of biologicals. For I believe—and perhaps my belief will be shared by many of the gentlemen present—that the coming way to cure a disease will be to prevent it.

I refer, of course, by such a paradoxical remark, to the question of immunity—both the “natural” and “acquired.” By “natural” we refer to the power of our bodies to resist infection. This power has probably been handed down by our forefathers to a certain point, and strengthened to a great extent by our exposure to attenuated forms of many prevalent pathogenic organisms. In a broad sense, “acquired” immunity, here, may be taken to mean both the condition of those who have passed through a mild or severe form of some disease and have produced their own protection against future invasion of that particular organism, and that of those in whom immunity has been produced, at least passively, by the injection of anti-bodies. These anti-bodies are usually contained in what we commonly know as antitoxins.

Of all antitoxins, the best known, and most widely used, is the diphtheria antitoxin. As the procedure in all is practically the same, it will be sufficient for me to explain the producer's side of this one only.

In 1883, the diphtheria bacillus was first described by Klebs, and in 1884, was cultivated on artificial media by Loeffler. Hence it is commonly known among bacteriologists, as the Klebs-Loeffler bacillus. In 1888, Roux and Yersin discovered the presence of toxin in broth cultures. This bacillus, and its power to produce toxin, is the foundation, the all-necessary starting point, in the production of antitoxin for diphtheria. We keep this bacillus constantly growing in the laboratory-incubators.

The culture now used by, practically, all the laboratories in the work, was obtained from a case of diphtheria, by Dr. Parks, of the New York City Board of Health, and has proved the strongest toxin-producer so far procured, although it has been grown for many years on artificial media.

After we have the bacillus, the next step is to get the maximum toxin-producer

*Read before the City of Washington Branch, April, 1914.

tion. This is done by growing it on specially prepared peptonized beef-broth. This broth must be made from fresh beef, freed from fat. To the extracted juice is added, $1\frac{1}{2}$ percent peptone and $\frac{1}{2}$ percent NaCl. It is then titrated, using phenolphthalein as an indicator. The acidity is reduced to 0.8. It is then flaked and sterilized in an autoclave at a temperature of 116° to 120° C., or about ten pounds steam pressure. This exposure to heat renders the beef broth sterile. It is then ready for inoculation.

This is done by transferring a small portion of membranous growth from our stock culture. The development is very rapid. In fact, the whole surface of the medium will be covered by a heavy membrane after twelve to eighteen hours' growth at 37° C. The growth is allowed to continue for from eight to ten days. The flasks are then taken from the incubator and examined microscopically. If pure, they are then titrated and should be found alkaline to phenolphthalein.

Filtering this culture through a germ proof filter, is the next step. After filtering, the toxin is then tested on guinea pigs to determine its strength.

This is done by injecting varying amounts. For instance, three pigs are selected, each weighing from 250 to 300 grams. They are injected subcutaneously, No. 1, 2, and 3, with 0.005 cc., 0.008 cc., and 0.01 cc. of toxin, respectively. The pig that survives is counted out of the test; the one that dies on the fourth or fifth day is taken to indicate the M. L. D. or minimum lethal dose of this particular toxin.

It is now ready for injection into the horse. I will say here that great care is exercised in selecting the animals for an antitoxin stable. They are kept in a quarantine stable until they have satisfactorily passed the test for glanders and tuberculosis. Temperatures are taken night and morning of all horses. When a horse is finally pronounced ready, the initial dose of toxin is given. This dose is usually about 0.1 of a cubic centimeter, and sometimes gives a very decided reaction. I have known on several occasions where a horse weighing from 1000 to 1200 pounds would be killed in from twenty-four to thirty-six hours following an injection of only 0.2 cc. of diphtheria toxin. The doses are gradually increased, as the immunity is established, until the horse will stand 1500 or even 2000 cc. of strong toxin. This amount would be sufficient to kill 3000 or more non-immunes. In many cases the horse will stand from 500 to 700 cc. of toxin without decided reaction. The blood is drawn from the jugular vein. From this point we will discuss antitoxin.

The blood is drawn into sterile jars containing sodium citrate solution, in sufficient quantity to bring the content to 2 percent. This prevents the coagulation, and allows the corpuscles to settle to the bottom of the jar. The jars of blood are kept in the ice box until the serum or plasma is ready to be decanted. The decanting is done by vacuum. The plasma is drawn into sterile containers. It is now ready for precipitation.

The method of precipitation has recently been decidedly improved upon by Dr. Benzhaf, of the New York Department of Health, and his method is now in use in our laboratory. I will here set forth the routine:

We first measure our plasma. To the total quantity is added 50 percent of a 4 percent NaCl solution. To the total quantity resulting from this mixture, is

added approximately 32 percent of a *saturated solution* of ammonium sulphate. This mixture is allowed to stand—usually over night. It is then heated in a water bath built especially for the purpose. The temperature of the mixture is brought to 60° C. and held there for ten minutes. It is then removed from the bath and filtered while hot through filter paper. This precipitation, called “first fraction,” has thrown down the euglobulin, which is collected on the filter paper, and, later, after being pressed to dryness, is discarded.

The filtrate is measured, and to the resulting volume is added, approximately, 38 percent ammonium sulphate in saturated solution. This we call our “second fraction” and results in the precipitation of the pseudo globulins, (and is high in antitoxin value). This precipitate is collected on the filter papers and is placed between absorbent or blotting paper and subjected to a great pressure in a press arranged for the purpose. By this means all moisture is extracted and the precipitate is scraped from the papers in the form of a dry, powder-like substance, which is immediately put into parchment bags and dialyzed in running water from six to ten days, during which time it is redissolved and practically freed from the salts which have been used in its precipitation.

The resulting antitoxin is now of a decided green color, and is ready for the preliminary filtration. This is accomplished by drawing it through a pulp paper by means of a vacuum pump. After this filtration, 0.8 percent sodium chloride is added and the antitoxin is ready to test.

The testing is an all-important feature and must be accurately and scientifically performed. The method of testing is as follows:

First. We must determine the L+ dose of our test toxin. The L+ dose is the quantity of poison, not only sufficient to neutralize one antitoxin unit, but it must contain excess sufficient to kill a 250 gram guinea pig on the fourth or fifth day. The exact dose now having been determined, this amount is mixed with varying dilutions of the antitoxin to be tested. For instance, a serum which is supposed to contain 300 to 400 units to the cc. is diluted as follows: 1:200, 1:250, 1:300, etc. One cc. of each of these dilutions is mixed with the L+ dose of the toxin in the injection syringes and allowed to stand at room-temperature for one hour, then injected subcutaneously into selected guinea pigs. If the animal receiving L+ plus the 1:250 dilution, lives, and the one receiving L+ plus the 1:300 dilution, dies, we know that the unit strength lies between these values and further tests will establish it almost accurately.

The strength determined, the antitoxin is filtered through germ-proof filters and one-tenth of one percent chloroform is added and thoroughly mixed.

This is now stock and is stored in the ice box at a temperature of 40 degrees where it is kept until filled into syringes and distributed to the pharmacist upon order.

I have here samples of antitoxin showing the various stages of its preparation, which I have tried, at least, to describe to you.

There are several other antitoxins, such as tetanus, antimeningococcus, streptococcus, and recently one has been developed for pneumonia at the Rockefeller Institute. A bulletin on this subject will soon be published.

In serums we have also the normal horse serum, which has been used extensively in the control of haemophilia with splendid results.

Vaccine now comes up for consideration. Until recently when one spoke of vaccine it meant only one thing to us all—smallpox vaccine. Since 1796 vaccination against smallpox has been practiced. This work was first done by Jenner, and his observations were published as far back as 1798. In spite of this lapse of time, the etiological factor which causes the disease is still unknown. We do know, however, that with successful vaccination and quarantine, the dreaded scourge has been robbed of many victims.

Vaccination today, is quite a different problem from the procedure of the past, and is gradually wearing down the prejudice held by so many, who were sufferers, either directly or indirectly, as a result of the unscientific method of charging our vaccine points directly from the lesions on the calf, or using the scab from the arm of one person to vaccinate another. In this way it was possible to carry infections and have very sore arms, or even much more serious consequences. Such danger at the present time is practically *nil*. For we now use great care in the selection of our seed lymph, and by so doing have now almost a pure vaccine. This is put on calves selected by and under daily inspection of a veterinarian. These animals are housed in a modern building, put up for this purpose alone, and kept in the best state of cleanliness. The calf, after vaccination, is kept under observation practically day and night, until the "take" is complete and the vaccine is ready to be removed and prepared for commercial use.

The "pulp," as we term the ripened vaccine as it comes from the calf, is brought to the laboratory and goes immediately into glycerin. The effect of the glycerin is to kill off the bacteria which have gotten into the vaccine during the period of incubation on the calf, leaving the true vaccine virus unharmed and still highly potent.

After weeks in glycerin the "pulp" is finely ground and fresh glycerin is added. It is then tested both bacteriologically and physiologically. The lymph having proved pure and potent is then charged on ivory points, or filled into capillary tubes, ready for use. The lymph will remain potent for a long time if kept under proper conditions. By "proper conditions," I mean that these points and tubes should be kept in a cool, dark place. These instructions, which are printed on every package, do not seem to be taken seriously by some pharmacists, and, consequently, the lymph dries and loses its potency much sooner than it should, and thence results the "failures" which not infrequently occur with all vaccines, a matter which is of no small moment to the physician, and of these cases, I assure you the producer is kept *well* and sometimes *harshly informed*. Within the past few days, a physician told me that he had to go to several places before he found one where vaccine was kept in an ice box. He had experienced trouble with vaccine kept on the shelf at room-temperature, and did not wish to have it repeated. I want to lay stress upon the fact that biological products should be kept in a cool and fairly constant temperature. If this rule is followed the results will be better for us all.

As an illustration of this, I will say that between February 5 and 19 of this year we had the opportunity to have our vaccine tested on about one hundred children in an institution of this city. The work was done by the physician of

the institution, and he reported 100 percent of "takes" in primary cases, with no commonly called "bad arms."

The recent development of bacterial vaccines has brought a new field, both to the laboratory and the pharmacist, and their use is rapidly becoming a routine with many physicians in treating furunculosis, otitis media, pyorrhea, gonorrhea—in fact, wherever pus production is present, and in septic conditions generally.

This treatment consists of making the vaccine from the bacteria or combination of organisms causing the pathological condition. This is done by growing the bacteria on suitable media, that is selecting the medium on which the best and most rapid growth takes place. After satisfactory development, the bacteria are washed off in sterile normal salt solution, and thoroughly shaken in a bottle containing beads. This is done to separate or thoroughly break up colonies or clumps of bacteria. This accomplished, they are exposed to heat sufficient to kill all the germs present. 0.1 percent to 0.2 percent trikresol is then added and the suspension, or emulsion as it is sometimes called, is allowed to stand over night.

The next day cultures are made on various media, both ærobic and anærobic, using from 1 cc. to 2 cc. for each tube. These are incubated for from two to four days, and, if they remain sterile, the vaccine is then ready to standardize, that is to count the bacteria in each cc. This procedure is the same as that used in determining the number of corpuscles in the blood.

After standardizing, any dilution desired lower than the original count can be made.

Not only does the injection of this vaccine control the infection, but produces an immunity that is more or less lasting against future recurrence.

This method of treatment is constantly being tried along new lines, and splendid results are being reported almost daily.

The theory is, that by the injection of the killed bodies of the bacteria, the opsonic index is raised and the body is able to successfully resist the invading bacteria. Raising the opsonic index means stimulating the action of the polynuclear leucocytes and preparing them to envelope the bacteria and look after their destruction. It might be said that you prepare your army to fight the foe.

This has been proved most conclusively in the use of typhoid vaccine in the Army and Navy, and also by the many injections made recently by the general practitioner. You are all, of course, more or less familiar with this work. To those of us who are following closely the study, it looks as if the practice would become even more general than the vaccination against smallpox.

In conclusion, I want to say, that the modern and very material advance in medical science, is being built on a more firm foundation, and the component parts of this foundation are, Anatomy, Physiology, Bacteriology, Pathology and Pharmacology. Let us each do what we can for their advancement and the benefit of mankind.

THE REVISION OF THE UNITED STATES PHARMACOPŒIA.*

JOSEPH P. REMINGTON, PH. M., CHAIRMAN, COMMITTEE OF REVISION.

The work of revising the United States Pharmacopœia is fast approaching completion, but, of course, it is impossible to announce a date of issue, because some pending and very important questions must be settled. It is expected, however, that printing in "galley" will begin July 1st.

Until 1906, the United States Pharmacopœia was accepted by the country as authoritative, when any one needed to use it for their benefit, but not authoritative when its tests interfered with what men called "business." This anomalous position was changed when the Food and Drugs Act made the Pharmacopœia the standard and the law of the land. The United States Pharmacopœia is only one out of thirty pharmacopœias used by other countries throughout the world.

The idea of an International Pharmacopœia, which would be authoritative, is regarded now as a dream of the future, but there is no good reason why all of the Pharmacopœias should not unite upon tests and rubrics, and, probably, the doses of medicines. The great difficulty in framing an International Pharmacopœia would be in selecting the articles of the materia medica and the preparations. The medical profession cannot be brought into harmony throughout the world with regard to the use of remedies against disease, and those found in an International Pharmacopœia would not be adequate, and it can readily be seen that such a book would be a very small one; as far as the United States is concerned many well-known and largely-used indigenous drugs would not be accepted by Germany, Russia, Japan, Austria and many other nations. A Pharmacopœia can never be an exploiter of new and untried remedies. That is not its function, and the book must contain a selection of drugs and medicines which are used in the various sections of the country, irrespective of special localities. Its title is the "Pharmacopœia of the United States of America." Internationalism is a grand idea and our fancy is tickled at the thought of one Pharmacopœia being used throughout the world, but the situation is not unlike that of universal peace, the disarmament of nations, and Church unity. It must be clear to everyone that, at this time, we are not ready for the culmination of these great movements. But there is no good reason why an earnest effort should not be made to induce the pharmacopœias of the world to accept as many subjects as possible upon which they can all agree; instead of an International Pharmacopœia, it would be much more practicable for each nation to have its own Pharmacopœia, with its own materia medica and pharmacy made to suit the people of the country, with an *international agreement on Standards*. This view seems to be substantially accepted by International Congresses, and every Pharmacopœial Commission hereafter will be expected to fall into line and at least make all of the very powerful and active remedies conform to one strength as, for instance, the fixing of the International Standard of arsenical preparations at one percent. An International Committee is at work endeavoring to frame tests for chemicals

*Read before New York Branch.

and assays, which will enable a physician to prescribe the best-known and most largely-used chemical substances of uniform purity throughout the world.

I am expected to speak more particularly of the present revision of the United States Pharmacopœia. It occupies a unique position; no Pharmacopœia of the world is revised upon the same plan. Pharmacopœias of the larger countries in the old world, are revised through a commission appointed by the Emperor, King, Queen, or ruler, but in the United States, the initiative comes directly from the people, and the medical and pharmaceutical professions, through a decennial convention, assembled at Washington, composed of delegates from all parts of the United States. Each body sends representatives who are believed to be most capable of determining the policy and general principles which should control the next revision. It has not been deemed wise to place the revision of such a work in the hands of men who belong to one political party, indeed your Chairman has never asked, and he does not know, how five men out of the fifty-one voted in the last presidential election, and if he did, it would make no difference in assignments of appointments. The reason given for the small honorariums or sums of money paid for services, has been the fear that money considerations would induce unworthy persons to make extraordinary political efforts to obtain control of the book to reward their friends or punish their enemies. The United States Government has been well represented in this revision, through its laboratories and the coöperation of the head of the Bureau of Chemistry, of the Department of Agriculture, Dr. Alsberg, and Dr. J. F. Anderson, Chief of the Hygienic Laboratory of the Marine Hospital Service. Several of the members of the Committee of Revision have official Government positions. It cannot be said that the Committee is not representative of the various branches of the healing art. The General Committee of 51, elected by the Convention of 1910, elect 15 of its members to have charge of the immediate revision. Each of these men become Chairmen of the Sub-committees and these Sub-committees are chosen for their especial fitness for the subject. Several of the members of the General Committee are on more than one Sub-committee. When the Executive Committee have reported on any branch of the work, the votes, in detail, from each member are reported, so that each member knows what is going on in each Sub-committee. The Executive Committee and the Chairman, both, have the right to appeal for a decision to the General Committee of Revision for a settlement. General questions, not falling immediately within the purview of a Sub-committee, have been referred to the General Committee directly. In this way, the consensus of opinion is obtained. This is a new plan for pharmacopœial revision, and is based upon the well known custom of deliberative bodies, and in fact, the principles underlying the Constitution of the United States.

The spirit which actuates both Committees and the Chairman is to get the best, without fear or favor. Publicity has been a prominent feature in this revision. For the first time in pharmacopœia building have the changes and standards and tests, been published in advance of the approval of the final text. This has been done to permit any one to frame a criticism or propose an improvement. This world-wide criticism or comment must have a limit fixed for the reception of comment or criticism, naturally, or the book would not appear for several years,

as it would be impossible to produce a work which could satisfy every criticism which could be made. Errors must, of course, be corrected whenever found and at once, but it is hoped, that with 50 or more experts reading proof, that every error will be detected before final printing.

The final draft on admissions and deletions must soon be forthcoming. There have been many admissions and more deletions. This subject has been thrashed over for nearly four years. The Convention disapproved of the admission of patented or proprietary preparations, mainly on the ground that everything in the Pharmacopœia should be free and open to all and that the Pharmacopœia should provide tests of identity and purity. If a manufacturer or owner will permit his synthetic or specialty to be introduced into the Pharmacopœia, he should sign an agreement giving to the Pharmacopœia such permission, otherwise he could secure whatever advertisement would come from the introduction of his specialty, and he might make any change in the appearance or the standard of strength or purity and the Pharmacopœia would have to frame standards and tests to suit the preparation sent out by the manufacturer. If the Pharmacopœia should introduce a synthetic without such an agreement, it would be possible for the manufacturer to have good grounds for a lawsuit and to demand an accounting and obtain damages for such loss as he believes he has sustained. In this connection a case was settled in Holland as follows:

"An action had been commenced by the Bayer Company, of Elberfeld, against a firm of wholesalers in Holland, for selling Aspirin Tablets which were not of their manufacture, thus infringing their trademark 'Aspirin.' The defense made to this action was that Aspirin was now included in the Dutch Pharmacopœia, and that, therefore, the word had come into public use and whatever rights Messrs. Bayer had previously, had now lapsed. The action was carried up to the High Court of Appeal in Holland, and Messrs. Bayer won their suit, the wholesalers being mulcted in damages, the Courts deciding that notwithstanding the word appears in the Dutch Pharmacopœia, Messrs. Bayer are still legally entitled to the word 'Aspirin' as their trademark."

If the Pharmacopœial Committee should decide to ignore the rights of an owner, and should introduce a synthetic without an agreement with him, no matter whether it was introduced under another name, the courts would rule in favor of the manufacturer or owner of the protected substance. Inasmuch as physicians can continue to prescribe the protected substance without let or hindrance, is it worth while, merely for the sake of seeing a synthetic in the Pharmacopœia to take such a step? The manufacturers of synthetics who have been consulted, have uniformly failed to give such permission and some have declared their intention of defending their rights through legal processes. An exception would probably have been made by an owner or manufacturer in a case of a patented or protected article, where the patent had a few months or probably a year to run, and, seeing a very moderate profit ahead, he might take advantage of the Pharmacopœia's introduction and give permission. The present Pharmacopœia, under the name of Acetphenetidin, admitted the extensively used and valuable phenacetin. These statements are made in order that you may understand the reasons which govern the Revision Committee in its decisions.

The Ninth Revision will differ from all those which have preceded it, mainly because much assistance has been rendered by manufacturing chemists and others, who have freely tendered their laboratory facilities and the services of their chemists, in trying out tests and standards and in perfecting detail. While this has greatly increased the correspondence, the time has been well spent because of the many valuable suggestions received. It has been necessary at times to arrange for hearings and conferences, and the effort has been made to invite every manufacturer or dealer having a special interest in the subject, to attend the hearings. A Committee of manufacturers was appointed, who were asked to get together, reconcile their differences and send a final draft to the Sub-committee. The Executive Committee of the U. S. P. did not accept every item in the report, but they did accept about 80 percent of the recommendations.

Conferences of the General Committee and the Executive Committee, have been held at the annual meetings of the American Pharmaceutical Association, and special conferences have been called in Philadelphia, of Sub-committees, with experts a number of times. In addition to this, the Committee has had valuable assistance from the local branches of the A. Ph. A. and State Pharmaceutical Associations. All of these communications have been tabulated, recorded and sent to the Sub-committees. In the preparation of the final text, by a system of collecting and recording by modern methods with card indexes, alphabetical lists and the valuable help of collaborators are grouped together, so that the editor may catch any suggestion which may correct an error or improve a process. Unlike many books, such as commentaries and text-books, a Pharmacopœia reflects the views of many persons, and is not in any sense the work of one man. It is constructive work and is republican, democratic and progressive. The plan is essentially American. There is a President and a Board of Trustees who have, during the work of revision, been kept in touch and have been supplied with circulars and the Executive Committee Letters. The Board of Trustees have the entire charge of financial affairs, making of contracts for the publication, and authorizing expenditures, but the work of revision is, of course, in the hands of the General and Executive Committees. The General Committee might be likened to the House of Representatives, and the Executive Committee, to the Senate. The Sub-committees have a parallel, in the Committees of the Senate and House of Representatives. The special Committees report to the bodies having the appointing or elective power.

For the first time in the history of Pharmacopœia making, the U. S. P. is using a method of publicity by printing before the issue of the book, in the pharmaceutical and medical journals, an abstract of the changes and standards, in order that these may be considered by all parties interested. These, must all be sent to the Chairman of the Committees of Revision before July 1st, the time fixed for beginning the printing. Any very important changes or errors discovered after July 1st, should be sent to the Chairman by telegraph.

It is not the intention, in the future, to wait for the usual period of ten years, to issue a supplement, and any addition or deletion which may become necessary, will be published, so that the book may be kept more fully abreast with the times. In this way, it is believed that the criticism made of the present and previous

pharmacopœias of being out of date, will be obviated, for the U. S. Pharmacopœial Convention is an incorporated and continuous body, each Convention taking over the property and effects of the previous Convention, new officers and committees being elected or appointed every decade.

The plan of revision has been worked out with the intention of providing the elements of stability and responsibility, and the experience of members gained in revision work, is a valuable asset in avoiding mistakes and errors of judgment. New men are elected to the Committee of Revision by the Convention, and a proper balance is sought to be maintained. Whatever criticism of this revision may be made in the future, it can never be said that every effort has not been made to have the work representative of all sections of the country.

The pharmacopœia is essentially a book of standards. Many men of many minds have contributed to its pages. It differs from ordinary books. It does not appeal to the sympathies or passions of men. It is a book without a plot. It advocates no propaganda, for *it*, itself is the propaganda. There is no exploiting of fads, no graft, no disposition to resent constructive criticism, and, now that the work is nearly finished, the Chairman declares that the sole object has been to provide pure, unadulterated, effective medicines of uniform quality, for the alleviation of pain and treatment of diseased conditions in the human race.

The lecture was illustrated with lantern slides as follows:

1. Text of the U. S. P. VIII.
2. Sub-committee No. 6 Bulletin, showing the first step in the revision—compiled criticisms and foreign standards.
3. Sub-committee No. 6 Bulletin, showing the first draft of modified text. Underlined portion differs from the U. S. P. VIII.
4. Sub-committee No. 6 Bulletin, showing the second re-drafted text as proposed for submission to the Executive Committee.
5. The Sub-committee report, as submitted to the Executive Committee.
6. Text submitted to the General Committee, for criticism and suggestions.
7. Publicity. Published Abstract of proposed changes in the text.
8. A page of the Report on Miscellaneous Galenicals, as submitted to the General Committee.
9. Circular-page, illustrating proposed text for type processes for fluidextracts.
10. Circular-page, showing a report on Inorganic Chemicals.
11. Circular-page, showing a report on Botany and Pharmacognosy.
12. Circular-page, showing a report on Assays.
13. Page, showing abbreviation and synonym to be inserted.
14. Page, showing proposed line-numbers for the U. S. P. IX.
15. Page, showing proposed paragraph numbers.
16. Page, showing proposed change in type for formulas.
17. Proposed title page, for the U. S. P. IX.

THE PHYLACOGENS.*

F. C. WALDECKER, M. D., NEW YORK CITY.

As time goes on we appreciate more and more the wisdom and farsightedness of the immortal Pasteur, who prophesied that the day would come when it would be possible to eradicate the infectious diseases by vaccination.

Bacteriology, from the time of Leeuwenhock in the latter part of the seventeenth century to the present day, is as interesting in its evolution as any subject which medicine provides. Its development extends over a period of two hundred years and, during this time, the foundation was laid for the rapid and important progress which has been made in the last three decades.

Bacteriology has revealed that certain micro-organisms produce certain diseases and to-day we are using, in the preparation of a variety of agents, these same bacteria for their own destruction. The value of these products, in the treatment and prevention of disease, is too well known to require emphasis.

Some may think that biologic therapy has grown like the proverbial mushroom, and that the workers in this field have been over-enthusiastic in bringing into use the many products of bacterial origin. But reflect, we have been using Antidiphtheric Serum for twenty years; bacterial vaccines have been in use almost fifteen years and Koch presented his first tuberculin to the profession twenty years ago.

Therefore, while at first thought, it may seem that discoveries and methods of treatment have been presented with unusual rapidity, the therapy has in fact grown but slowly.

At the beginning of the present decade much interest was manifested by the medical profession, in and about San Francisco, concerning the reports of the extraordinary results following the use of a new class of bacterial derivatives in the treatment of acute and chronic infections. The products used were originated by Dr. A. F. Shafer of California, who presented his discovery to the profession through the San Joaquin Medical Society at Fresno, California, in October, 1910, and later through the San Francisco Medical Society in January, 1911.

These products, derived from bacteria, were denominated Phylacogens, from the Greek words, *φύλαξ* and *γενναίω*, meaning "to produce a guard."

The principle upon which Phylacogen Therapy is founded, is that of mixed or multiple infection. Three theories are advanced by Shafer. First, that the human subject is at all times the host of a great variety of micro-organisms, and harbors pathogenic bacteria without harm to itself, during periods of physiologic resistance at or above par. When physiologic resistance is subnormal, and especially when solution of tissue-continuity occurs, the bacteria harbored assume pathogenic activity. Second, that practically all infections are mixed; that only in rare instances, is there infection by a single species of micro-organism;

*Read at the meeting of the Philadelphia Branch, American Pharmaceutical Association, April 7, 1914.

that while one species may, and usually does, predominate, the pathologic process engendered by it is accelerated and intensified by organisms of other species which are present. In other words, that in the course of an infectious disease, manifestations are due, not only to the effects of a single species of organisms, the specific infection, but also in part to the influence of other organisms, whose pathogenic role is not insignificant, and which must be combated in any successful scheme of therapeutics. Third, the growth of micro-organisms, infecting the human subject, can be arrested, and their effects neutralized, by the administration of metabolic substances generated during the development of germs in artificial culture media.

Shafer does not contend that these premises are original with himself, but that he has recognized their pathologic and therapeutic significance, and that his system of therapy by means of Phylacogen is new and a great step forward.

Instances of mixed infections will occur to all of you, as for example, gonorrhea shortly after onset, tuberculosis, and coryza. In tuberculosis, for instance, secondary infection is generally admitted to be the cause of fever, loss of weight, purulent expectoration, destruction of tissue and such other manifestations as appear in advanced tuberculosis. Further evidence of the existence of mixed infections, is the extensive use of so-called combined bacterial vaccines. Physicians many times have had cases of infection that they could improve but could not cure, through the use of a vaccine prepared from a single organism, while cure was rapidly established through the employment of a vaccine containing the predominant organism and such other bacteria as were associated therewith.

The Phylacogens are neither bacterial vaccines nor serums. They are sterile aqueous solutions of substances generated by bacteria grown in artificial media. They are prepared by cultivating a number of the common pathogenic organisms, such as the several staphylococci, streptococcus pyogenes, streptococcus rheumaticus, diplococcus and pneumoniae, bacillus coli communis, etc. The cultures are incubated at 37° C. for a specified time, the organisms are then killed, a preservative consisting of .5% phenol added and the fluid is then filtered through porcelain. This filtrate is basic Phylacogen and commonly known as Mixed Infection Phylacogen. It is used in the preparation of the specific Phylacogens.

The specific Phylacogens for the treatment of rheumatic and gonococcal infections, erysipelas and pneumonia, are prepared by adding an equal quantity of the basic filtrate, (Mixed Infection Phylacogen), to a filtrate obtained from the predominating organism. In other words, in the preparation of Rheumatism Phylacogen, 5 cc. of a filtrate made from the streptococcus rheumaticus, is added to 5 cc. of basic Phylacogen.

Culture tests are made of each lot of Phylacogen prepared, to determine whether the completed product is sterile. Co-incidentally, safety tests of the same preparations are made by injecting relatively large doses subcutaneously, into a series of animals. Should these investigations result satisfactorily, the product is passed as safe.

As to the physiological action of these preparations, little is known, and, for that reason, Phylacogen Therapy may be objected to under the charge of empiricism. While knowledge of the action of Phylacogen is highly desirable,

the absence thereof is not a valid criticism. Pasteur knew nothing of the action of his virus for the prevention of hydrophobia; Jenner knew nothing of the action of vaccine for the prevention of smallpox; the Jesuit Fathers knew nothing of the action of cinchona bark in the treatment of malaria. These men were empirics, but who at this date minimizes the value accruing to the human family from the use of smallpox vaccine and quinine?

Investigators are busy in attempting to reveal the mysteries in the physiological action of Phylacogen. Progress in research of this kind is slow, but progress has been made, and in all probability considerable light will soon be shed upon this most interesting subject.

Clinically, Mixed Infection Phylacogen is indicated in infections classed as surgical. In this connection, it must be understood, of course, that the Phylacogens are not what might be called "pus absorbers." When pus is present, it must be liberated. Mixed Infection Phylacogen is being used with success, in the treatment of infections in a variety of locations following surgical procedure and other injuries, in puerperal infections, empyema, osteomyelitis, otitis media, carbuncle, etc., etc. It is also being employed in the treatment of hay fever and bronchial asthma. A short time ago one would hesitate to suggest the use of a bacterial product in the treatment of hay fever or asthma, as their causative factors have for years been considered other than bacterial. Suffice it to say, however, that a number of patients have received benefit from the use of appropriate vaccines or of Mixed Infection Phylacogen, and a number have been cured. So-called "asthma," due to cardiac or renal disease, or produced reflexly through pathology in the nose or throat, are not appropriate cases for Phylacogen treatment.

Gonorrhea Phylacogen is indicated in the treatment of acute and chronic complications of gonorrhea. Reports of its efficacy in acute urethritis have appeared but their number is too few to establish its value in this condition. The common complications amenable to Gonorrhea Phylacogen, are acute and chronic prostatitis, vesiculitis and the arthritis, commonly known as gonorrheal rheumatism.

Erysipelas and Pneumonia Phylacogen, as their names imply, are used respectively in the treatment of erysipelas and pneumonia, the latter only when due to the pneumococcus.

Rheumatism Phylacogen is the one of the series that has been used most largely. It is indicated in the treatment of acute and of chronic arthritis due to the streptococcus rheumaticus, and such sequelæ as chorea and neuritis.

The Phylacogens are administered either subcutaneously or intravenously. The subcutaneous method is the one of choice. It accomplishes every purpose in the majority of cases, although the results are not as rapid as from intravenous administration. As a routine measure, the subcutaneous treatment has every advantage and the intravenous method should be employed in those few cases which do not yield to the less heroic procedure.

The injection of Phylacogen is usually followed by reaction, local, systemic, or both. These reactions may be slight or marked, depending principally upon the general condition of the patient and the size of the dose. From intravenous administration, there is no local manifestation other than the slight trauma inci-

dent to injections of this kind. Following the subcutaneous injection more or less local pain, redness and swelling may result. This depends largely, however, upon the site chosen for injection. As a rule injections made slowly into locations of loose tissue are rarely followed by marked reaction, while the reaction is usually greatest when large amounts are given rapidly into the leg or arm.

The systemic response appears usually within six hours. This is manifested by chill, lasting from a few to thirty or more minutes, and an increase in the temperature. Depending again upon the general condition of the patient and the size of dose, the systemic reaction may be mild or pronounced, and following an excessive dose, there may be added to the chill and increase in temperature, nausea, vomiting, diarrhea, great depression and general numbness, etc. Such symptoms, of course, are undesirable, and when they occur, it means that the dose has been in excess.

Clinicians, at this writing, are not agreed as to the necessity of pronounced reactions, but many are of opinion that, with marked systemic response, the cure is more rapidly established. Others hold that mild reaction only is necessary.

The degree of reaction in any patient, it must be remembered, lies entirely in the size of the dose. By well controlled dosage, pronounced reaction can almost always be avoided.

The dose of Phylacogen, as with all drugs, varies with the individual patients, but, as a rule, the initial dose subcutaneously is from 1 to 2 cc. Intravenously, the initial dose is from $\frac{1}{8}$ to $\frac{1}{4}$ cc. Subsequent doses, at intervals of from twelve to forty-eight hours, are to be gradually increased, when given subcutaneously, by from 1 to 2 cc.; when given intravenously by from $\frac{1}{8}$ to $\frac{1}{2}$ cc. The usual maximum subcutaneous dose is 10 cc., the maximum dose intravenously 5 cc.

Before closing this paper, which of necessity is but a brief outline of this new therapy, I wish to take the opportunity to say a few words concerning diagnosis. It has been said that once the diagnosis is established, the treatment is easy and I think we can all agree to the correctness of this assertion in its broad sense. Diagnosis is difficult and the success of any treatment will depend upon the accuracy with which it is established. The development of exact methods of diagnosis, has advanced rapidly during the past few years and the information furnished by various laboratory tests will many times establish the diagnosis and nearly always assist in its determination. In such a protean disease as "rheumatism," for instance, accurate diagnosis is often not easy, and possibly in no other condition are so many errors in diagnosis made. This is due, in great part, to the lack of a satisfactory etiological and pathological classification of the arthritides and in part to the close clinical resemblance between them.

It has been remarked that we, as physicians, are prone to call almost any pain about the joints "Rheumatism," because then we know what we mean, although we do not know what we are talking about. One eminent medical man says, "Rheumatism has sometimes turned out in my experience to mean aortic aneurysm, cancer of the pleura, tabes dorsalis, osteomyelitis, spondylitis deformans, bone tuberculosis, syphilitic-periostitis, lead poisoning, morphine habit, alcoholic neuritis, trichiniasis, and gonorrheal infection.

Acute rheumatic fever and many of the chronic rheumatic conditions are,

beyond doubt, caused by bacteria, but to maintain that all cases of chronic rheumatism are due to germ activity, demands more evidence than we can at this time provide. Naturally, a product of bacterial origin can render no service in a condition in which the causative factor is not bacterial.

The diagnosis being correct and the case suitable, Phylacogen Therapy will, in the great majority of instances, yield prompt and pleasing results, some actually astonishing. These filtrates will produce satisfactory effects more speedily than bacterial vaccines and they are successful in many conditions in which the older agents fail. However, the Phylacogens will not accomplish the impossible—they are not “cure-alls.” They have been employed for four years, during which time several thousand cases have been reported, and these indicate a high percentage of successes. Most failures, when they occur, may be considered due to lack of care in diagnosis, to indiscriminate dosage or to faulty technique.

Phylacogen, Vaccine and Serum Therapies, with the possible exception of surgery, are as exact in their scientific application as any therapy which medicine provides. Fulfill the requirements demanded, by a careful selection of cases and intelligent use and they will serve their purpose well.

BUSINESS EXPENSES IN GERMANY.

Apotheker Eugen Roth, of the Ludwig-Wilhelm Apotheke in Carlsruhe, has published for some years in the “Pharmazeutische Zeitung” a table showing the percentage of expense in relation to turnover. Especially interesting in the fact that during the past fourteen years the turnover resulting from dispensing has declined and that from counter-sales increased. The following table shows the percentage participation of the various items of expenditure in 1913, compared with the total turnover:

	Percent		Percent
Drugs and chemicals.....	13.8	Glass utensils.....	2.01
Specialties	26.67	Insurance	1.36
Dressings	1.60	Freights and postage.....	0.85
Indiarubber goods.....	0.43	Salaries and wages.....	15.43
Mineral waters.....	1.55	Heating and light.....	0.74
Stationery (labels, boxes, etc.)...	1.21	Various	0.86

The expenditure, not including taxes, rent, and interest, amount to 65.12 per cent of the turnover.—*The Chemist and Druggist* (London).

Reports of A. Ph. A. Committees

REPORT OF COMMITTEE ON UNOFFICIAL STANDARDS.

The following portion of the report of the Committee on Unofficial Standards relates to certain crude drugs and chemicals suggested for inclusion in the next revision of the National Formulary, and by order of the Council is published in the JOURNAL in order to afford opportunity for discussion before the standards proposed are finally adopted.

Manufacturers, importers, analysts, and others interested in any of the proposed standards, are requested to send their criticisms and comments to the chairman of the committee, Geo. M. Beringer, Ph. M., 501 Federal St., Camden, New Jersey.

APPROVED MONOGRAPHS SUBMITTED AS STANDARDS FOR UNOFFICIAL DRUGS AND CHEMICAL PRODUCTS.

AGARICUS.

White Agaric. Larch Agaric.

1. The dried fruit body of the fungus *Polyporus officinalis* Fries (Fam. *Polyporaceae*) collected from *Larix Pinus* Linné and *Larix Siberica* Ledeb.

2. Light, fibrous, somewhat spongy pieces of irregular shape, grayish-white to pale-brown externally; yellowish and resinous internally; fracture tough, fibrous; while friable it is difficult to powder.

3. The powder examined under the microscope shows numerous non-septate, narrow, mycelial threads and many cubical crystals of Calcium Oxalate .001 mm. to .002 mm. in diameter.

4. To boiling Alcohol it should yield not less than fifty percent of a resinous extract. Upon incineration it should yield not more than 2 percent of a white ash, rich in phosphates.

ALBUMEN OVI RECENS.

Fresh Egg Abumen.

The freshly separated liquid white of recently laid eggs of the hen *Gallus domesticus* Temminck (Fam. *Phasianidae*).

ASCLEPIAS.

Asclepias. Pleurisy Root.

1. The dried root of *Asclepias tuberosa* Linné (Fam. *Asclepiadaceae*).

2. Usually cut or broken pieces, of variable size of an irregularly fusiform root from 10

to 20 cm. long and 2 to 5 cm. thick, and occasionally branched, externally pale orange-brown, annulate above, the surface roughened by numerous fine intersecting grooves; bark thin; fracture tough, the broken surface granular and white, with inconspicuous pale-yellow wood bundles and large white medullary rays; odor slight; taste bitterish and disagreeable, somewhat acrid.

BAPTISIA.

Baptisia. Wild Indigo Root.

1. The dried root of *Baptisia tinctoria* (Linné) R. Brown (Fam. *Leguminosae*).

2. Fleshly, 1.25 to 4 cm. thick usually cut into elongated cylindrical pieces; the crown 5 to 8 cm. thick, more or less warty and marked by stem scars; outer surface dark-brown, transversely warty, or the thicker pieces covered with a soft and friable corky layer, bearing few branching rootlets; fracture tough, the fractured surface whitish; bark-section radially striate, wood section inconspicuously radiate, porous; nearly odorless; the bark tastes bitter and acrid, the wood nearly tasteless.

DELPHINIUM.

Larkspur Seed.

1. The dried seeds of *Delphinium Consolida* Linné and *Delphinium Ajacis* Linné (Fam. *Ranunculaceae*).

2. Irregularly tetrahedral, or by pressure

somewhat triangulate, acute at one end, obtuse or rounded at the other, about 2 mm. long and equally broad or slightly narrower; surface black or blackish-brown, deeply and narrowly furrowed, the furrows intersecting so as to give a sharply tuberculate appearance to the surface, with serrate or toothed edges; testa crustaceous; kernel whitish, fleshy; embryo small, in fleshy endosperm; odor very little; taste bitter, afterward biting and acrid.

DIOSCOREA.

Dioscorea. Wild Yam Root.

1. The dried rhizome of *Dioscorea villosa* Linné (Fam. *Dioscoreaceae*).

2. Knotted and woody, elongated, sparingly branched, 6 to 12 mm. thick, somewhat compressed, bearing scattered nodular projections at the sides, elongated, slender tough roots underneath and stem-scars on the upper surface; pale brown, surface more or less scaly from the partly detached thin outer layer; fracture short but not weak, the fractured surface whitish or pale-brown, with numerous small wood bundles; odorless; taste starchy and slightly acrid.

FRAXINUS.

White Ash Bark.

1. The dried bark, deprived of the corky layer, of the trunk of *Fraxinus Americana* Linné (Fam. *Oleaceae*) and probably of other species of *Fraxinus*.

2. In flat pieces of varying length and width 3-6 mm. thick; externally yellowish or pale brown, sometimes with ridges of a warty nature and fissures of a grayish-brown color with markings of lichens; inner surface, pale brown to yellowish, striate; fracture very uneven, somewhat fibrous; odor faintly aromatic; taste bitter, weakly acrid.

3. Ash not over 10 percent.

FRUCTUS RUBI.

Blackberry.

1. The fresh ripe fruit of varieties of *Rubus nigrobaccus*, Bailey, or *Rubus villosus* Aiton (Fam. *Rosaceae*).

2. An aggregate fruit, ovate to oblong-rounded or slightly pointed, composed of numerous shining black drupelets attached to an esculent receptacle; pericarps externally smooth or with only a few hairs (*R. villosus*); mesocarps fleshy, juice purple-red; endocarps hard, black, surfaces deeply wrinkled; taste sweet and slightly acid.

FRUCTUS RUBI IDAEI.

Raspberry.

1. The fresh ripe fruit of varieties of *Rubus Idaeus* Linné (Fam. *Rosaceae*).

2. An aggregate fruit, globular or hemispherical with a concave depression at the base where separated from the receptacle, composed of twenty or more small rounded polygonal succulent drupelets; pericarps externally red, hairs numerous; mesocarps fleshy, juice red; endocarps small stones with wrinkled surfaces; odor characteristic, aromatic; taste pleasant, sweet, acidulous.

3. For pharmaceutical purposes, the black raspberry, the fresh ripe fruit of cultivated varieties of *Rubus occidentalis* Linné (Fam. *Rosaceae*) may be used either in part or entirely in place of the red raspberry.

FRUCTUS SOLANI CAROLINENSIS.

Horse-nettle Berry.

1. The air dried ripe fruit of *Solanum Carolinense* Linné (Fam. *Solanaceae*).

2. Globose, slightly depressed and somewhat shriveled and wrinkled in drying .8 to 2 cm. in diameter, orange-yellow, glabrous, fleshy, two-celled, many-seeded, calyx and pedicle usually persistent; calyx stellate-pubescent, deeply five-lobed, the lobes ovate or ovate-lanceolate, acuminate and enclosing half or more of the berry; seeds orbicular, flat, yellow, smooth shining; odor pepper-like; taste bitter and acrid.

3. Ash about 5 percent.

GEMMAE POPULI.

Balsam Poplar Buds. Balm of Gilead Buds.

1 The air dried closed winter leaf buds of *Populus nigra* Linné and *Populus balsamifera* Linné (Fam. *Salicaceae*), collected early in the spring. Balsam poplar buds should be kept in tightly closed containers of glass or tin.

2. Conical, pointed, up to 2 cm. long and 2 to 5 mm. thick, consisting of closely imbricated scales, externally brown and glossy, glutinous with fragrant resin; odor pleasant, balsamic; taste aromatic, bitter.

JUGLANS.

Juglans. Butternut Bark.

1. The dried bark of the root of *Juglans cinerea* Linné (Fam. *Juglandaceae*) collected in autumn.

2. In quills, curved strips or chip-like pieces. 3 to 10 mm. thick; deep chocolate-

brown color on both surfaces and throughout, except for the faint intersecting whitish radial and tangential lines seen on transverse section; outer surface smoothish or somewhat warty, the inner bearing fragments of adhering thin stringy fiber; fracture short, rather weak, slightly fibrous; taste faintly aromatic, bitter, somewhat pungent and acrid.

JUNIPERUS.

Juniper Berries.

1. The carefully dried ripe fruit of *Juniperus communis* Linné (Fam. *Coniferae*). Juniper berries should be kept in air-tight tin or glass containers. Old or insect-infected fruit should not be used.

2. Nearly globular, about 8 mm. in diameter; externally smooth, shining black-brown to purplish-black with a blue-gray bloom, at the apex a three rayed furrow marks the cohesion of the three fleshy bracts forming the pericarp; internally loosely fleshy, greenish-brown, containing numerous large schizogenous cavities; seeds three, triangular ovate, hard, brown, with large uneven oil glands on the surface; odor aromatic; taste sweet, pleasant, terebinthinate, slightly bitter.

3. Ash not more than 5 percent.

4. Sections examined under the microscope exhibit a pericarp consisting of an epiderm of a single row of rounded polygonal cells filled with a brown granular substance, at the sutures of the bracts these become blunt papillae, a hypoderm of 2 or 3 rows of brown-red, wide collenchyma thickened at the angles; the fleshy portion (mesophyl) composed of loose irregular parenchyma with large oval canals and traversed by fibro-vascular bundles with areolated fibers; a sclerenchymatous ring of 6 to 8 rows of very thick cells with pitted walls many enclosing prismatic crystals of calcium oxalate; the seed-testa shows a layer of 2 to 10 rows of stone cells with radial markings on the walls and each enclosing a polygonal crystal of calcium oxalate; endosperm and embryo rich in fat and aleurone.

LAC VACCINUM.

Cow's Milk.

The fresh whole milk, complying with the legal standard, of the domestic cow *Bos taurus* Linné (Fam. *Bovidae*.)

MENYANTHES.

Menyanthes Leaves.

Buckbean. Marsh Trefoil.

1. The dried leaves of *Menyanthes trifoliata* Linné (Fam. *Menyanthaceae*).

2. Glabrous; petioles 10 to 15 cm. long, stout but soft and weak, the base more or less sheathed with broad, thin and membranaceous, somewhat translucent stipules; blade ash-green, trifoliate; leaflets sessile or very short-petioled 5 to 8 cm. long and usually about two-thirds as broad, obovate, blunt, entire or occasionally coarsely and unequally crenate; odor slight but characteristic; taste decidedly bitter.

3. Ash not more than 10 percent.

OLEUM AURANTII AMARI CORTICIS.

Oil of Bitter Orange Peel.

1. A volatile oil obtained by expression from the fresh peel of the Bitter Orange, *Citrus Aurantium* Linné *subspecies amara* Linné (Fam. *Rutaceae*). It should be kept in small amber-colored well-stoppered bottles, in a cool place. Oil that has developed a terebinthinate odor should not be dispensed.

2. A pale yellow liquid, having the characteristic, aromatic odor of orange and an aromatic somewhat bitter taste.

3. Soluble in four volumes of Alcohol, the solution should be neutral to litmus paper; also soluble in all proportions in Absolute Alcohol and in an equal volume of Glacial Acetic Acid.

4. Specific gravity: 0.846 to 0.854 at 25° C.

5. Its optical rotation dextrogyrate from 92° to 94° in a 100 mm. tube at 25° C.

6. Introduce 50 cc. of Oil of Bitter Orange Peel into a 200 cc. three bulb, fractionating flask. Distil the oil at the rate of 2 cc. per minute until 5 cc. of distillate has been collected. The angle of rotation of this distillate of 10 percent of the oil, should be equal to or slightly higher than that of the sample before distillation.

OLEUM AURANTII FLORUM.

Oil of Orange Flowers. Oil of Neroli.

1. A volatile oil distilled from the fresh flowers of the Bitter Orange, *Citrus Aurantium* Linné *subspecies amara* Linné (*Citrus vulgaris* Risso, *Citrus Bigaradia* Risso) (Fam. *Rutaceae*). It should be kept in small amber-colored well-stoppered bottles in a cool place, protected from light.

2. A pale yellow, slightly fluorescent, neut-

ral liquid, having the fragrant odor of orange blossoms and an aromatic, at first sweet then somewhat bitter taste.

3. Specific gravity: 0.868 to 0.875 at 25° C. Optical rotation is dextrogyrate from 1° 30' to 5° in a 100 mm. tube at 25° C.

4. Shaken with a concentrated solution of sodium bisulphate it assumes a permanent purple-red color.

5. Soluble in an equal volume of Alcohol, the solution having a violet fluorescence and a neutral reaction to litmus paper. Soluble in 2 volumes of 80 percent Alcohol, the solution becoming cloudy on further addition of Alcohol of same percentage.

OLEUM BERGAMOTTAE.

Oil of Bergamot.

1. A volatile oil obtained by expression from the rind of the fresh fruit of *Citrus Bergamia* Risso (Fam. *Rutaceae*). It should be kept in small amber-colored well-stoppered bottles in a cool place, protected from light.

2. A green or greenish-yellow liquid, neutral or only faintly acid, having a characteristic fragrant odor and a bitter taste.

3. Specific gravity: 0.875 to 0.880 at 25° C. Optical rotation dextrogyrate from 8° to 24° in a 100 mm. tube at 25° C.

4. Two volumes of the Oil, when mixed with one volume of Alcohol, should give a clear solution and this should not become turbid on the further addition of Alcohol. Soluble in two volumes of 80 percent Alcohol with not more than a slight cloudiness and no separation or oil globules. Soluble in all proportions in Glacial Acetic Acid.

5. If a weighed portion, about 2 gm. of the Oil be evaporated in a tared dish, on a water-bath, until the odor has completely disappeared, a soft green, homogeneous residue should be left, amounting to not more than 6 percent of the Oil (fixed oils).

6. To 2 gm. of Oil of Bergamot add 10 cc. of alcoholic potassium hydroxide, V. S., evaporate to dryness and incinerate. Extract the ash with water and acidify with diluted nitric acid, no cloudiness should be produced on addition of silver nitrate T. S. (Chlorinated Compounds).

7. To 2 gm. of Oil of Bergamot add 20 cc. of half-normal alcoholic potassium hydroxide V. S. and heat the mixture in a flask on a water-bath filled with boiling water under a reflux condenser for a half hour. Cool the

mixture and add 100 cc. Distilled Water and titrate with half-normal sulphuric acid V. S., using phenolphthalein as indicator, not more than 12.6 cc. of acid should be required, indicating a minimum content of 36 percent of ester, calculated as linalyl acetate, in the oil.

OLEUM MYRCIAE.

Oil of Myrcia.

Oil of Bay.

1. A volatile oil distilled from the leaves of *Pimenta acris* Wight (Fam. *Myrtaceae*). It should be kept in small well-stoppered amber-colored bottles, in a cool place, protected from light.

2. A yellow or brownish-yellow liquid having a pleasant aromatic odor and a pungent spicy taste.

3. Specific gravity: 0.965 to 0.985 at 25° C. Optical rotation laevorotatory from 2° to 6° in a 100 mm. tube.

4. With an equal volume of Alcohol, Glacial Acetic Acid, or Carbon Disulphide, it yields slightly turbid solutions. The alcoholic solution is slightly acid to litmus paper.

5. When mixed with an equal volume of a concentrated solution of sodium hydrate, it forms a semi-solid mass.

6. If 2 drops of the Oil be dissolved in 4 cc. of alcohol, and a drop of ferric chloride T. S. be added, a light green color will be produced; and if the same test be made with a drop of diluted ferric chloride T. S., prepared by diluting the test solution with four times its volume of water, a light bluish coloration will be produced, which soon disappears.

7. To 3 drops of the Oil, contained in a small test-tube, add 3 drops of sulphuric acid, cork the test-tube and allow the mixture to stand for half an hour, a resinous mass should be obtained. On adding to this mass 4 cc. of diluted alcohol, vigorously shaking the mixture, and gradually heating on a water-bath to the boiling point, the liquid should remain nearly colorless, and should not acquire a red or purplish-red color (distinction from oil of pimenta and oil of cloves).

8. Shake 1 cc. of the Oil with 20 cc. of hot water, the water should not give more than a scarcely perceptible acid reaction with litmus paper.

9. If, after cooling, the liquid in the test above be passed through a wet filter, the clear filtrate should produce, with a drop of ferric

chloride T. S., only a transient grayish-green, but not a blue or violet, color (absence of phenol).

OVUM GALLINACEUM.

Hen's Egg.

The recently laid egg of the hen *Gallus domesticus* Temminck (Fam. *Phasianideae*).

PASSIFLORA.

Passion Flower. Passion Vine.

1. The dried herbage of *Passiflora incarnata* Linné (Fam. *Passifloraceae*) collected after some of the berries have matured.

2. Stems glabrous or slightly pubescent above, striate, 6 to 8 mm. in diameter, of variable length, woody, hollow, the cavity about one-half the diameter; bark very thin, greenish or purplish; wood very porous and bordered on the inner side by a thin layer of pith; fracture uneven, of the stem smooth, of the bark coarsely fibrous.

3. Leaves more or less broken in drying, rather thick, glabrous or often pubescent, nearly orbicular in outline, base cordate, deeply 3 to 5 lobed, lobes ovate, acute, finely serrate, petioles 1 to 5 cm. long with 2 glands near the summit. Tendrils numerous and closely coiled.

4. Flowers solitary, axillary, peduncles as long as the petioles, usually 3 bracted; calyx cup-shaped 4-5 lobes, lobes linear, imbricated, cuspidate, corona purplish; petals 4-5 dirty yellow; ovary oblong, stalked; stamens monadelphous in a tube about the stalk of the ovary, separated above, anthers narrow, versatile.

5. Fruit 4 to 5 cm. long, an ovoid many-seeded berry; externally green or yellow, shriveled and wrinkled; seeds flat, ovate, yellowish to brown arilled.

6. Taste and odor slight.

7. Ash not over 12 percent.

PUMEX.

Pumice.

1. A substance of volcanic origin, consisting chiefly of complex silicates of aluminum, potassium and sodium.

2. Very light, hard, rough, porous gray masses or a gritty, gray-colored powder.

3. Permanent in the air, odorless and tasteless. The dry masses usually float on water.

4. Boil 10 gm. of Pumice with 50 cc. distilled water for one-half hour, adding water from time to time to maintain approximately the original volume and filter; the filtrate

should be neutral to litmus paper, and one-half of this filtrate when evaporated and dried at 110° C. should yield not more than 0.01 gm. residue (*limit of soluble substances*). The remaining half of the filtrate after slightly acidulating with hydrochloric acid should not yield a blue color with Potassium Ferrocyanide T. S. (absence of iron).

5. Boil 1 gm. with 25 cc. diluted hydrochloric acid for one-half hour, adding water from time to time to maintain approximately the original volume, then filter the liquid; the filtrate should yield upon evaporating to dryness, igniting and quickly weighing, not more than 0.05 gm. of residue.

SAMBUCUS.

Sambucus. Elder Flowers.

1. The air dried flowers of *Sambucus canadensis* Linné or of *Sambucus nigra* Linné (Fam. *Caprifoliaceae*) separated from the peduncles and pedicels.

2. Small, about 2 to 3 mm. broad, shriveled; calyx superior, five lobed; corolla cream colored to brownish-yellow, rotate, flat or slightly campanulate, regularly five lobed; stamens five inserted at the base of the corolla and alternating with its lobes, filaments slender, anthers oblong, yellow; pollen ellipsoidal or tetrahedral and rounded, covered with finely punctate markings and three parallel longitudinal slits; taste slightly bitter; odor faintly sweet and aromatic.

3. Ash white and not more than 8 percent.

SENECIO.

Senecio. Life Root.

1. The dried overground portions of *Senecio aureus* Linné (Fam. *Compositae*) gathered when flowering.

2. Stems 3 to 6 dm. long, if entire bearing a basal rosette of leaves; sparingly clothed with successively smaller leaves and bearing at the summit several yellow heads in a loose corymb, white floccose when young, but mostly glabrous when in flower; radical leaves on long slender petioles, mostly of rounded form 5 to 7 cm. broad, the base often cordate, the summit rounded, the margin crenate-dentate; stem-leaves gradually changing from the shape of the radical leaves to lyrate pinnate, then pinnatifid and sessile, and at length clasping, oblong and incised; heads slender peduncled, 12 to 25 mm. broad, the lance-linear involucre scales in about 2 series, closely appressed, rays about 10,

bright-yellow, disk flowers very numerous, small, bearing a glabrous akene and a white pappus; odor characteristically aromatic; taste bitter, slightly astringent and distinctly acrid and pungent.

STRONTII CARBONAS.

Strontium Carbonate.

1. It should contain at least 99 percent of Strontium Carbonate ($\text{Sr CO}_3 = 147.62$).

2. A white powder, odorless and tasteless.

3. Insoluble in water, soluble with effervescence in diluted hydrochloric, nitric or acetic acids. Addition of diluted sulphuric acid to these solutions produces a white precipitate.

4. 1 gm. should yield a clear solution with 10 cc. of diluted hydrochloric acid (*sulphate*).

5. 10 cc. of a 1:100 solution, solution being effected by a slight excess of nitric acid added to the water, should not become more than slightly opalescent at once on adding silver nitrate T. S. (limit of *chloride*).

6. Dissolve 1 gm. in water by means of a slight excess of acetic acid, and dilute to 100 cc. On adding to 10 cc. of this solution 5 drops of potassium dichromate T. S. no turbidity should develop within five minutes (limit of *barium*).

7. .5 gm. dissolved in diluted hydrochloric acid should not respond to the U. S. P. Time Limit Test for *heavy metals*.

8. Shake 2 gm. with 25 cc. of water and filter, on evaporation of the filtrate and drying the residue at 100°C . it should weigh not more than 0.01 gm. (limit of *soluble substances*).

9. Dissolve about 1.5 gm. (accurately weighed) in 30 cc. of hydrochloric acid V. S. and titrate the excess of acid with sodium hydroxide V. S., using methyl orange as indicator. Each cc. of normal acid consumed is equivalent to 0.07381 gm. strontium carbonate.

SUCCUS CITRI.

Lime Juice.

1. The expressed juice of the ripe fruit of *Citrus medica*, var. *acida* Linné (Fam. *Rutaceae*). 100 cc. should contain from 5 to 10 gm. of total acids, calculated as crystallized citric acid.

2. A clear or slightly turbid, pale yellow or yellowish-green liquid, having the characteristic odor and taste of limes.

3. Specific gravity: 1.025 to 1.040 at 25°C .

4. To 5 cc. of Lime Juice add 20 cc. solu-

tion of potassium hydroxide and heat in a 100 cc. flask together with 0.5 gm. of granular aluminum or aluminum foil on a water bath for 10 minutes, no odor of ammonia should be noticeable at any time during the heating (absence of *nitrates*).

5. If .1 cc. of barium chloride T. S. be added to 5 cc. of clear filtered Lime Juice, only a slight turbidity should be produced after standing two minutes (limit of *sulphates*).

6. If .1 cc. of nitric acid followed by .1 cc. of silver nitrate T. S. be added to 5 cc. clear filtered Lime Juice, only a slight opalescence should be produced after standing two minutes (limit of *chlorides*).

7. If 5 cc. each of sulphuric acid, alcohol and Lime Juice be heated, no odor of acetic ether should be developed (limit of *acetates*).

8. Add 1 cc. of an aqueous solution of potassium acetate (1 to 3) to 5 cc. of filtered Lime Juice and then add to the mixture alcohol in excess, a slight cloudiness may occur but no crystalline precipitate should be formed within 15 minutes (limit of *tartrates*).

9. Upon evaporation and ignition until free from carbon, Lime Juice should not leave more than 0.5 percent of ash. The ash from 5 cc. of lime juice when dissolved in a few drops of nitric acid and diluted with water should show not more than traces of phosphate when tested with ammonium molybdate T. S.

10. Lime Juice should contain not more than 0.04 percent of sulphurous acid (SO_2) when tested by the method of the U. S. P. IX Revision for determining SO_2 in gelatin.

11. Upon distilling 200 cc. of Lime Juice with excess of calcium hydroxide until 100 cc. of distillate is obtained, the specific gravity of the distillate should indicate not more than 2 percent of absolute alcohol by volume in the distillate or 1 percent in the lime juice (limit of *alcohol*).

12. Shake 10 cc. of Lime Juice acidified with sulphuric acid with 25 cc. of ether, separate the ether and evaporate it to dryness, the residue should not be crystalline and, when dissolved in about 3 cc. of water, should not produce a purplish color on addition of one drop of ferric chloride T. S. (*salicylic acid*).

13. Shake 10 cc. of Lime Juice acidified with sulphuric acid with 25 cc. of ether and

separate the ether and evaporate it to dryness, the residue should not be crystalline and, when dissolved in 3 cc. of water and carefully neutralized with ammonia water, should not produce a flesh colored precipitate on the addition of one drop of ferric chloride T. S. (*benzoic acid*).

14. Dilute 20 cc. of Lime Juice with 100 cc. of water, filter, if necessary, and add 4 cc. of diluted hydrochloric acid. Into this solution immerse a piece of wool which has been boiled in a very dilute solution of potassium hydroxide T. S. and then washed in water, and boil for 5 to 10 minutes. Remove the wool, wash thoroughly in water, and boil in a very dilute solution of hydrochloric acid. After washing out the acid with water, boil with about 200 cc. of 2 percent solution of ammonium hydroxide until the color on the wool, if any, is dissolved. Remove the wool, and add a slight excess of hydrochloric acid to the solution. Immerse in this solution another piece of wool which has been treated with potassium hydroxide solution in the same manner as the first. Boil. This second piece of wool should not be dyed (*aniline dyes*).

SUCCUS POMORUM.

Fresh Apple Juice.

The freshly expressed juice of sound, ripe, sour apples, the fruit of cultivated varieties of *Pyrus malus* Linné (Fam. *Rosaceae*).

TRIFOLIUM.

Trifolium. Red Clover Blossoms.

1. The dried flowering heads of *Trifolium pratense* Linné (Fam. *Leguminosae*).

2. Heads ovoid with rounded summit, mostly 12 to 25 mm. long and broad, shriveled, purplish and more or less brown from drying, consisting of many small papilionaceous flowers, crowded together and clothed at the base with broad, pointed, ciliate stipules of a pale green color with darker veins, and which may or may not be accompanied by diminutive trifoliate leaves. Flowers 12 to 15 mm. long; calyx about two-thirds the length of the corolla, the pilose campanulate tube a little longer than the four short nearly equal teeth and shorter than the narrower fifth one, calyx-teeth subulate, tapering; petals united into a tube below, the standard longer than the wings but when recurved appears shorter; stamens diadelphous (9 and 1); style slender; odor faintly aromatic

and somewhat tea-like; taste sweetish, then slightly bitter.

TRILLIUM.

Beth Root.

1. The dried rhizome of *Trillium erectum* Linné (Fam. *Liliaceae*) and closely allied species of *Trillium*.

2. Rhizome oblique, globular, oblong or obconic, truncate below, terminated by a small bud surrounded by a sheath of scarios leaf bases, annulated by leaf scars and fissured by stem scars; .6 to 2.5 cm. wide by .6 to 5 cm. long, more or less compressed laterally, rootlet scars in several concentric rows on the under side in the upper portions; externally yellowish to reddish-brown; internally of a pale yellow; fracture somewhat uneven with a more or less spongy appearance; odor distinct; taste bitter and acrid with a sensation of warmth in the throat and when chewed causing an increased flow of saliva.

3. Ash not more than 5 percent.

VERBENA.

Verbena. Blue Vervain.

1. The dried overground portion of *Verbena hastata* Linné (Fam. *Verbenaceae*) collected when flowering.

2. In broken or cut pieces of stout, obtusely quadrangular stems which bear opposite leaves and terminal interrupted panicles of spikes of blue flowers; rough, hairy throughout, except the corolla, the tube of which is externally pubescent; petioles 12 to 25 mm. long; leaves 6 to 12 cm. long, lanceolate, acuminate and acute, coarsely and sharply serrate, or the lower hastately lobed, deep green above, paler beneath, conspicuously veined; spikes erect, cylindraceous, densely flowered, each flower subtended by a lanceolate acute bract; calyx adherent, a little more than half the length of the corolla, tubular, 5 lobed, the mouth slightly oblique; corolla small, bright blue, salver-form, sub-equally 5 lobed; stamens adnate to the corolla tube, included, didynamous; fruit dividing at maturity into four one-seeded parts; odor heavy, especially if dampened; taste bitter and disagreeable.

VITELLUM OVI RECENS.

Fresh Egg Yolk.

The freshly separated yolk of recently laid eggs of the hen *Gallus domesticus* Temminck (Fam. *Phasianidae*).

Of General Interest

CALIFORNIA; 1915!

Representatives from the various branches of the pharmaceutical profession located in and about San Francisco met in enthusiastic conference in that city on the evening of April 20, to take preliminary steps toward the entertainment of the members of the profession who will be in attendance upon the various meetings of the craft which are to be held in that city during the maintenance of the Panama Pacific Exposition. An organization was effected with Mr. J. A. Sanford, the President of the California Pharmaceutical Association, as chairman. The meeting was addressed by Mr. James A. Barr, Chief of the Bureau of Conventions and Societies for the Exposition, who told of the painstaking work of his department, in planning for the proper accommodation of the many associations, who are to have their meetings at the Golden Gate during the fair.

Mr. Fred I. Lackenbach spoke of the warm responses which he had received, from all sources, to his suggestion that the A. Ph. A. hold its meeting in San Francisco in 1915. Addresses were made by several other gentlemen, in support of Mr. Lackenbach's proposition, and the meeting voted to appoint a committee of three to "work out" the details of plans for the accommodations of the members of the profession who attend the fair.

A SYMPOSIUM ON THE PROPOSED HARRISON BILL.

At the meeting of the Philadelphia Branch of the A. Ph. A., a number of letters were read on the subject of the so-called Harrison Bill, now pending in the U. S. Senate, and in view of the grave importance of the provisions of this bill to the pharmacists of the country, we give space to print these letters in the columns of the JOURNAL, trusting that a full and frank discussion of the matter will redound to the advantage of the profession.

Washington, D. C., May 4, 1914.

Dear Prof. Cook:

With reference to the so-called Harrison Bill and the misunderstanding of same by many retail pharmacists, permit me to discuss the question briefly and to say that this is largely due to their misconception of the necessity for such legislation by the Federal Government and also their lack of understanding of the provisions of the pending measure and what it is intended to accomplish.

The necessity for the so-called Harrison Bill was not made manifest by the medical profession, drug trade or any of its allied branches. It was the result of careful study, after due investigation, by Federal officers, covering a period of several years, into the evils of drug addiction all over the United States. The appalling conditions unearthed in Philadelphia and other large cities, where school children of tender age had contracted the drug habit, and the fact that a large majority of crimes the past ten years, and especially in the South, were directly traceable to the habitual use of narcotic drugs, led the Federal Government, through its officers, to originally draft a bill which had for its object the absolute control of narcotic drugs, so that they could be sold and used for medicinal purposes only.

This bill being so drastic in its provisions, and the knowledge that, if passed, it would cause no end of trouble for those who of necessity would be required to handle such drugs, led the American Pharmaceutical Association to consider the proposition and to suggest the advisability of the formation of a Conference, whereby all affected interests could come together on common ground, discuss the question and agree upon something feasible yet effective, that would not be unworkable nor prove a burden and at the same time would carry out the original object, the proper protection of the public. It therefore then is a public health measure, and not one, as some seem to think, which will grant special privileges to certain classes.

The American Pharmaceutical Association, in bringing together the Conference, acted with the noblest of objects in view, the welfare of the public, yet at the same time they have conserved the interests of the retail pharmacists as far as possible and have succeeded in removing what would have been a burden, namely, the keeping of records of all

sales of narcotic drugs and the making of returns of the same. * * *

(Then follows a brief review of the field covered by the bill as already printed.—Ed.)

By comparing the sections of the amended "Harrison Bill" with the bill as originally proposed, it will be seen that the burdensome task of keeping a record of all sales of narcotic drugs and annually making returns of same, has been eliminated through the efforts of the National Drug Trade Conference, that was organized through the efforts of the American Pharmaceutical Association, and instead, records of purchases are provided for and returns are to be made only when demanded. Is not this work of the American Pharmaceutical Association to be commended and has not the organization conserved the welfare and interests of the retail pharmacists?

As this is a revenue measure it will require all dealers to obtain a license and further provides that the duplicate order blank shall be purchased from the collector of internal revenue, the license-fee is small and the price of the blanks nominal, so that while it is a revenue measure, it will furnish revenue sufficient only to properly carry the act and its enforcement.

With this act in operation and the coöperation provided whereby the present state officials can obtain information necessary for the enforcement of state laws, it will then become unnecessary for the various states to enact new laws, present state laws being quite sufficient if enforced; if not, they can be amended.

The enforcement of present state laws, with this act in operation, will reduce illicit traffic in narcotic drugs to the minimum. That is all that is expected, and it therefore then should receive the support of every self-respecting retail pharmacist in the United States.

A careful study of the provisions of this proposed act leads me to point out that the legitimate retail pharmacist will have but few burdens thrust upon him by its enactment into law, and that the necessary extra labor entailed will be more than compensated for by the good he will do toward humanity, preventing future drug-addiction, overcome the wrecking of individuals and homes and the prevention of crimes, consequently I believe every effort should be put forth to assist in

securing the passage of the bill, thereby cleaning out the dope-sellers and at the same time assist in placing our calling in the position to which it is entitled and where it will be more respected.

Sincerely yours,

S. L. HILTON.

April 30, 1914.

My Dear Professor Cook:

I am pleased, indeed, to learn that the Philadelphia Branch of the American Pharmaceutical Association is to discuss the so-called "Harrison Bill" and its relation to the retail drug trade. It appears somewhat unfortunate that drug associations in various parts of the country have not discussed this proposed legislation in as temperate and as thorough a manner as might have been done if more accurate information regarding the object and scope of the proposed legislation had been presented.

The so-called Harrison Anti-Narcotic Bill, usually referred to as "H. R. 6282," cannot in any sense be considered a regulatory measure and will at best only secure for state and local officials the necessary information to make existing laws operative. This information is to be secured by utilizing the taxing power of the Federal Government in such a way as to impose a nominal license-fee on all who are in any way engaged in the sale or distribution of certain enumerated drugs. In addition to the license-fee, the law also requires that all sales of the enumerated drugs be recorded in a specific way, the method outlined being designed to impose the minimum of trouble to the dealer and to secure the maximum information for officials entrusted with the enforcement of Federal, state or municipal laws and regulations.

How essentially necessary authentic sources of information really are, to enforce local laws, has been amply shown in the state of Pennsylvania, in connection with the cocaine law, and has been further emphasized in the state of New York, where the recently enacted Walker cocaine law was found to be quite inoperative because of the promiscuous introduction of cocaine from without the state, and the development of the illicit traffic by peddlers and others in no way connected with legitimate drug business.

That much misleading information has been published from time to time in regard to the extent of the abuse of narcotic drugs must

be admitted, but from the retail pharmacist's point of view, the opposition that has been evidenced to the enactment of the Harrison Bill has been altogether unfortunate, in that the public at large has been misled into interpreting this opposition as a justification of the frequently-made charge that retail druggists and men connected with the drug business generally, are primarily to blame for the very widespread misuse of opium and coca, their alkaloids and derivatives. It is for this latter reason alone, that it appears altogether unfortunate that the members of the drug trade have evidenced any, even passive objection, to the enactment of the Harrison Anti-Narcotic Bill, as adopted by the House of Representatives last June. The adoption of the various amendments that have been offered to the Committee on Finance of the Senate, and more recently in the Senate itself, do not in any way improve the measure as a source of information, and if embodied in the law as finally enacted, would serve to increase, unnecessarily, the difficulties of enforcing the law without securing any reasonable amount of additional information for the benefit of persons entrusted with the enforcement of local regulatory measures.

From the point of view of the retail druggists and members of the drug trade generally, it would appear desirable to endorse any reasonable legislation that will secure the necessary information to clearly place the onus of the drug abuse where it rightfully belongs, and if it should develop that members of the drug trade are to blame for the promiscuous use of drugs of this type, druggists themselves should be the first to insist that the continuation of such abuse be corrected by additional legislation, and thus clearly show that the promiscuous distribution of habit-forming drugs is not recognized in any way as being a part of the legitimate traffic in drugs and remedial agents.

Very truly yours,

M. I. WILBERT.

My Dear Professor Cook:

Mr. White has handed me your letter of April 29, 1914, with the request that as Counsel for the N. A. R. D. that I answer the same.

In reply I have to say that should the Harrison Bill be so drafted so as to include all parties handling narcotics, and place them under regulations, which will apply with equal

force to all alike, it will be of the greatest benefit. But should this bill pass in a shape so that it will apply unequally to the different classes of people who handle narcotics, it will not only be inefficacious, but it will create such bad feeling and friction as will make its enforcement well nigh impossible.

When Mr. Henry of your city was here I took pains to explain this situation to him and he no doubt will be glad to furnish you any details regarding the legislation.

Yours very truly,

ALONZO H. STEWART.

Dear Dr. Cook:

It gives me a real pleasure to discuss the so-called "Harrison Bill" for consideration by the Philadelphia Branch, and in doing so, I am not unmindful of the fact, that my views regarding the merits of the so-called "Harrison Bill" differ or at least have differed on some vital points from the views as held by two members of the Philadelphia Branch who are also members of the National Drug Trade Conference, and I must take it somewhat for granted, that the views held by said members of the Philadelphia Branch are largely the views of the Branch membership. In this connection I feel called upon to say, that I have always approached the subject as much as possible from the view point of the retail pharmacist seeking to serve best the public need and welfare.

You request a brief contribution, and brevity will be my endeavor, though I must point out, that the many important features will permit brevity only at the expense of clearness and adequacy. The discussion as you say is to be on the so-called "Harrison Bill," in its amended form as now before the Senate, and I take this to mean "H. R. 6282, Calendar No. 213."

The Harrison Bill, in its present form represents an exercise of the taxing power of the Federal Government, and is incidentally only an exercise of its control over interstate commerce, all for the purpose of providing necessary regulation for the distribution of narcotics, which the several states are either unable or unwilling to provide, and frequently indifferent to enforce, in so far as they can provide them. The taxing power is exercised nominally only, not so much with a view of yielding revenue, as with a view of affording a constitutional ground for Federal activity. Constitutional limitations will

not permit the Federal Government to prescribe in direct terms who may or may not sell or distribute within the several states, but to a large extent this can be accomplished by indirection based upon state legislation. On that account a proper Federal law will need to give every person the right to pay the proposed tax, and thus become registered as a dealer in narcotics. Now it may be argued, that under the circumstances the requirement for a \$1.00 tax which all can pay, will not be very helpful, because any drug fiend will gladly pay such a tax of \$1.00 to secure the right of purchase and possession, by becoming a dealer, and then simply supply his personal wants. However, the Harrison Bill, as drafted, gives the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury, the right to make needful rules and regulations, for carrying out the provisions of the Act, and this authority would seem to be wide enough to prescribe such regulations as will successfully limit the right to become registered as a dealer, to such persons who in fact are dealers, so that there would be but little danger that one who intends merely to be a consumer, could secure the right of possession as a registered dealer. This feature might possibly have been strengthened, but to attempt to do so may not have been expedient. Assuming, that, under this requirement, the right of possession for further distribution can be successfully limited to actual dealers, it must be granted, that, to this point, nothing more has been secured but what already exists, because the supply of narcotics for illegitimate use to-day comes from dealers of some sort, and there is no need evidently at present, for illegitimate users to become nominally dealers. It follows, that whatever benefit we are to secure from the proposed Federal legislation, must depend upon the greater restrictions which are placed upon the present dealers, most of whom we must assume will be entitled to registration under the intended Act. It is here, where the authority and power of the Federal Government is dependent entirely upon what it may not do directly, but what it may do to a large extent by indirection. To accomplish by indirection what the Federal Government may not do directly, there has been adopted a record system which has been embodied in the Harrison Bill, and, presumably, for the proper enforcement of a revenue measure the

distribution is required to be evidenced by a record of some sort. If this requirement for a record were made applicable to every distribution a large measure of success would seem to be assured. The entire frame work of the Harrison Bill contemplates that the drugs may reach the consumer only through sources, which by state law are authorized to alone supply the consumer for legitimate purposes. This result is secured by making all other distribution dependent upon having an Official Order Form, which of course can be had only by registered dealers. Since the entire narcotic evil ultimately comes from the traffic, which reaches the consumer, the all important question is, whether the control sought to be secured by indirection is sufficient in that respect. If the control over the drug and its distribution to the consumer, is incomplete or insufficient, then the entire proposed legislation is condemned to failure, for every other feature of the bill is merely an incident to the ultimate aim of limiting distribution entirely to legitimate final use and consumption. As already stated, the success of the Federal Act in limiting consumption of the drug to legitimate purposes is greatly dependent upon existing proper state legislation, always provided of course, that the control and supervision sought by indirection, through record requirement, is made uniformly applicable, so as to reach every case in which the drug is distributed for consumption. In my opinion, generally speaking, existing state laws are sufficient to act as a basis upon which indirect Federal control can be built. To me it seems, that the sufficiency of the Harrison Bill is therefore dependent upon the question of whether it aims to be uniformly applicable. Not considering at this point preparations which contain minimum quantities and which are exempted, the Harrison Bill if otherwise so drawn as to be enforceable, will because of the record requirement, limit successfully all distribution by retail pharmacists to consumers on prescriptions exclusively, and thus this source of supply for the consumer will be restricted to legitimate use. The bill requires with one unfortunate exception, that every distribution to the consumer be evidenced by a record in the form of a physician's prescription. Since the right to write prescriptions is limited throughout to certain classes, who are licensed to do so under state law, and since the right to fill prescriptions is limited to an-

other class licensed by state law, it would appear, that by making a record requirement in the form of prescriptions, one source of supply to the consumer will be sufficiently safeguarded. Up to this point the provisions of the Harrison Bill command utmost respect. Right at this point it fails, and, if unchanged, it will be largely a useless measure representing an enormous waste of time, energy and trouble. By Sub-section (a) of Section II, of the Harrison Bill, as advocated by the National Drug Trade Conference, and as contained therein, altogether because of the action of said conference, the distribution by physicians, dentists and veterinarians to the consumer are to be altogether without the need for record requirement. Under the bill a physician, dentist or veterinarian may distribute ten ounces of cocaine during a day and not be required to show what he has done with them, further than to say, that he has used them in the course of his professional practice. The fundamental idea of the Harrison Bill, is to control the existing evil by means of a system of record keeping. We may assume, or at least hope, that this would be largely successful, but the fundamental idea is not carried through to a logical conclusion, and while the law contemplates that the consumer may secure narcotics from about two hundred and fifty thousand physicians, dentists, veterinarians and pharmacists, it would enforce the fundamental idea with which success is hoped for, as against only less than fifty thousand, and would ignore it altogether with reference to the other, about two hundred thousand. If the fundamental idea underlying this proposed legislation means success, if uniformly carried out, it must be doomed to failure if applied to only one-fifth of those to whom it then should apply.

It has always been, and is now, my judgment that the physician, dentist or veterinarian, who would assume the functions of a pharmacist, should be governed by the exact same legal requirements and restrictions. It is my contention that the illegitimate traffic in narcotics is not by any means confined to possible wrong doers who are druggists, but that at least an equal amount may be placed at the doors of medical men. Therefore, to stop up the loopholes with respect to wrongdoers who may be found among only one-fifth of all who are to have the right to supply the consumer, is to make

a useless effort. It is reasonable to assume, that the improper traffic, which may now be carried on by some who constitute one-fifth of the total number, will be readily transferred, if necessary, to those who are now found among the other four-fifths to be guilty of such improper traffic.

Already I come to appreciate that my intended brief contribution is running away from me, and my further remarks will need to be confined to very brief statements. As a whole, the general intent and outline of the Harrison Bill, in view of constitutional limitations, should find approval. It means to accomplish the desired end by comparatively simple method. It places no particularly burdensome requirements upon either the manufacturing, wholesale or retail pharmacist. The method adopted for controlling and supervising all distribution among all dealers is likely to be effective. The rights of the legitimate retail pharmacist are not interfered with any more than is absolutely necessary, and no fair-minded pharmacist should complain with reference to the restrictions placed upon him, excepting in the matter of some important detail to which I mean to refer, but which it even now seems understood will be changed. But what is the use of giving expression to many things which are commendable, when primarily because of one practical defect the entire proposition is useless, and will produce no practical good. Even if everything else contained in the bill proves to be an exercise of the highest intelligence and as perfect as human mind can make, it is doomed to failure, so long as four-fifths of all who may lawfully supply the consumer, are not included within its most important provision.

Other defects to which I would point particularly are:

1st. That pharmacists who would fill a prescription for narcotics, are forced to know under penalty of fine and imprisonment, that the prescription is written by a physician who is also a registered dealer in narcotics.

2nd. The provision in Sub-section (b) of Section 2, which specifically limits the right to fill prescriptions to pharmacists. In my opinion such a provision in a Federal act is not constitutional. The exact same result is secured by substituting the word "dealer" for the word "pharmacist," and then because of legislation which exists in the

several states, only dealers who are pharmacists will be permitted to fill prescriptions.

3rd. Both Sub-Sections (a) and (b) of Section 2, in their present form, seriously endanger the constitutionality of the entire act, but this danger will be largely removed if the word "dealer" is substituted for the word "pharmacist," and if the exception and discrimination, with reference to record requirement as now made in favor of physicians, is removed.

All of these objections have been pointed out by the last Annual Convention of the N. A. R. D., and though the National Drug Trade Conference has been unwilling to admit or say, that it has acted on these objections, because so pointed out, the fact nevertheless remains that it has adopted changes which largely meet the objections, in all but the matter of requiring record keeping on the part of the physician when he assumes the functions of a pharmacist. Even in this respect, the Executive Committee of the National Drug Trade Conference has of late found itself compelled to advocate some record requirement, but in the form proposed it is wholly insufficient, because a dispensing physician could meet the requirement by entering in a book that he had dispensed one (1) ounce of cocaine on the fifth day of

May, without stating to whom and in what quantity he had dispensed it to each of the separate parties. So far as I have been able to measure the needs with reference to record keeping by dispensing physicians, etc., it should be exactly the same as is now in the bill made applicable to pharmacists, and on the other hand, administration by the physician himself to the patient in cases of emergency should not require record keeping.

There are, of course, other provisions in the bill which deserve attention in its discussion, but I am sure that I have taken up enough time and feel also that others from whom you will hear are better prepared to discuss them. To be concise with reference to them all, I advocate such changes as are now advocated by the National Drug Trade Conference, excepting only its late proposition for record keeping on the part of the dispensing physician, which is insufficient to meet the needs of the case. I believe that every person, be he physician, dentist, veterinarian or pharmacist, who would supply the consumer with narcotics other than administration in cases of emergency, should be made to make, have and show the exact same kind of a record for every distribution of the drugs.

Very truly yours,

FRANK H. FREERICKS.

PERSONALITY.

Personality implies intelligence and self-consciousness. A beast is an individual, but not a person. The mere animal feeds itself, but is not conscious of itself. The seat of personality is the center of all our bodily and mental activities. The idea of the bodily structure does indeed enter into the general conception of the person, but it is related to it just as our clothes are related to our bodies—as a mere adventitious appendage. It is not essential to the reality of the person, as that which constitutes a man's self survives the body; it is not essential to the identity of the person, as that remains unchanged amid all the changes of the body. The personality of a human being is centered in that which thinks and reasons, and wills; which loves, and fears, and hopes; which suffers, enjoys and feels.—*George Bush.*

Editorial Notes and Announcements

JAMES H. BEAL, Editor.....Scio, Ohio

ERNEST C. MARSHALL, Acting Editor,
63 Clinton Building, Columbus, Ohio

The Association does not accept responsibility for the opinions of contributors. Offensive personalities must be avoided.

Under the rules of the Postoffice the JOURNAL can be regularly mailed only to bona-fide paid subscribers. Subscriptions and association dues should be sent to the Treasurer, H. M. Whelpley, 2342 Albion Place, St. Louis, Mo.

All communications for insertion in the JOURNAL, or respecting advertising, requests for back numbers, and claims for missing numbers should be sent to the Acting Editor, 63 Clinton Building, Columbus, Ohio.

Claims for missing numbers will not be allowed if sufficient notice has not been given of change of address, and in no case if received later than sixty days from the date of issue.

REPRINTS.

If the request is made at the time copy is submitted, authors will be furnished with not to exceed 50 reprints, without cover, of papers accepted for publication in the JOURNAL.

Larger numbers of reprints will be supplied by the Stoneman Press Co. at the following prices, provided the order is received before the type has been distributed:

- 100 copies, 4 pages, no cover, \$2.50, with cover, \$4.50.
- 200 copies, 4 pages, no cover, \$3.00, with cover, \$5.50.
- 50 copies, 8 pages, no cover, \$2.75, with cover, \$4.50.
- 100 copies, 8 pages, no cover, \$3.50, with cover, \$5.00.
- 200 copies, 8 pages, no cover, \$4.50, with cover, \$6.50.
- 50 copies, 12 or 16 pages, no cover, \$4.00, with cover, \$5.50.
- 100 copies, 12 or 16 pages, no cover, \$5.00, with cover, \$6.50.
- 200 copies, 12 or 16 pages, no cover, \$6.50, with cover, \$8.00.

Orders for reprints may be sent either to the Editor, or to the Stoneman Press Co., Columbus, Ohio.

Under the heading, "The Pharmacist and the Law," will be found important amendments to the rules and regulations for the enforcement of the Food and Drugs Act. Under the amended rules the reception, by the Secretary of Agriculture, of guaranties from manufacturers and dealers, and the issuance of serial numbers, will hereafter be discontinued and all guaranties now filed will be stricken from the files and their serial numbers cancelled, and the use of such numbers is prohibited after May 1, 1915. The amendments further provide important regulations concerning the form of guaranty which may be given to dealers, in regard to their purchases and the manner by which it should be communicated, and relieves dealers from danger of prosecution when goods are purchased under such guaranty.

The entire pharmaceutical profession of the country, as well as its members located in Ohio, are indebted to Prof. George B. Kauffman for his successful efforts to stay the unwise and extravagant attempts of ignorant officialism in Ohio, to annoy the members of the profession with absurd construction of the laws.

Without Prof. Kauffman's efforts in behalf of the sane construction of the insecticide laws, recently passed in Ohio, every druggist in the state would have been put to great annoyance and expense, but by his action in organizing the druggists to oppose the Agricultural Commission, a permanent injunction has been granted by the courts and a needed lesson has been given to officials everywhere, that a sane interpretation must be given to all laws, and that justice and common sense are the foundations upon which all laws should be based.

A CORRECTION.

To the Editor:

Referring to the last paragraph on page 662, of the May issue of the JOURNAL, allow me to correct the statement therein, which implies that A. Schleimer introduced the use of cacao butter in making tablets.

As early as 1902 Edmund White (who now is President of the Pharmaceutical Society of Great Britain) and R. A. Robinson, Jr., contributed a paper which was read before the Dundee meeting of the British Pharmaceutical Conference, in which they proposed a mixture of one part of oil of theobroma and three parts of starch as a general excipient for tablets. At the Bristol Conference, in the following year, Edmund White and Henry Rodwell went further into the subject, and showed that by the use of an emulsion of theobroma the method could be used on a large as well as on a dispensing scale.

Yours very truly,

F. A. UPSHER SMITH.

<>

THE AMERICAN DRUGGISTS' FIRE INSURANCE CO.

The regular quarterly meeting of the Executive Board of The A. D. F. I. Co. was held on May 15 and 16, all of the members of the Board being present.

The business for the first quarter of the year was shown to have made splendid progress, the insurance written during that time amounting to \$3,834,934.70, at a net premium of \$39,889.30, which shows an increase over the business of the first quarter of the preceding year amounting to \$632,761.37, at a premium increase of \$6,603.91.

Fire losses of the company for the first three months of 1914, amounted to \$19,875.78, and the expense charged against the first quarter amounted to \$11,162.40.

On the 31st day of March, the company had in force 7216 policies for insurance, amounting to \$13,039,857.70, at a premium of \$133,856.15. During the first three months of the year the company saved its policyholders \$13,296.40 in their premium expense.

College and Society

MASSACHUSETTS COLLEGE OF PHARMACY.

The Forty-sixth Annual Commencement of the Massachusetts College of Pharmacy was held in Horticultural Hall, on Thursday, May 14. The Class Day program, at 2 p. m., was followed, at 3 o'clock, by the graduating exercises. The Class Day address of welcome was delivered by Charles Patrick Norton, the class history was read by Edward Louis Faucogney, and Joseph Hugh Cooney gave the oration. The prophecy came from Ralph Elliott Coburn. Alice Gardner Coleman made the Class Will, John Douglas Glancy, of the post-graduate section of the class, read an essay on Safe-guarding the Milk Supply, and the Farewell Address was delivered by Robert Edson Bemis.

President C. Herbert Packard presided at the graduating exercises. The prayer was made by the Rev. Frederick A. Wilmot, and the Hon. Samuel W. McCall delivered the Commencement address. Mr. McCall spoke of the importance of pharmacy as a profession and cautioned the graduates to have a care—in this age of specialization—that in their devotion to their work they do not allow themselves to become narrow, and he suggested that an active interest in the social, political and industrial problems of the day would, by fostering a broad open-mindedness, counteract the tendency to think and work along one line only.

The candidates for degrees were introduced to the President by Dean Theodore J. Bradley, who made a brief but thoughtful address to the class. As Mr. Lyman W. Griffin, the Secretary of the College, called the roll of the candidates for graduation, the President conferred the degrees, with some appropriate remarks to each individual student, afterward speaking to the class as a whole in his usual happy and forceful way.

Prize Nominations to Membership in the A. Ph. A. were awarded the following graduates

Joseph Hugh Cooney, for highest rank in senior organic chemistry; awarded by John G. Godding.

Emil Hermann Trumpold, for highest rank

in senior pharmacy; awarded by Prof. E. H. LaPierre.

Charles Patrick Norton, for highest rank in senior analytical chemistry; awarded by Prof. T. J. Bradley.

Robert Edson Bemis, for highest rank in senior materia medica.

Herman Jacob Epstein, for highest rank in senior general chemistry; both awarded by Pres. C. H. Packard.

The music for the afternoon was by the Salem Cadet Orchestra.

List of graduates, 32 for degree of Graduate in Pharmacy (including four women), and seven for the degree of Pharmaceutical Chemist:

Degree of Graduate in Pharmacy—Arthur Henry Barnes, Jr., Robert Edson Bemis, Elmer William Bennett, William Charles Bruzga, Herbert Francis Carbonneau, Ralph Elliott Coburn, Alice Gardner Coleman, Joseph Hugh Cooney, Joseph George Dion, Everett Leslie Emery, Herman Jacob Epstein, Edward Louis Faucogney, Edward Rudy Gifford, William Wallace Gifford, Nora Marceline Gobie, Kevork Gostan Gostanian, Charles Connor Hearn, Moses Jacobson, Bertram Francis Jones, Samuel Lourie, Emma Clare MacDonnell, Hortense Merrill, Howard Chamberlain Newton, Charles Patrick Norton, Frederick Vincent Palladino, Albert Solomon Pearlman, Samuel Kalil Saleeby, Earl Fuller Smith, Clarence Thompson, Eli Salmon Troupin, Emil Hermann Trumpold, John Francis Turner.

Degree of Pharmaceutical Chemist—Thos. Call Armstrong, Roy Chester Charron, Nicholas Ernest Dyer, John Douglas Glancy, Max Mackler, George Allen Moulton, Jr., Edward George Nagle.

The dinner of the Alumni Association complimentary to the class of 1914, at 6:30 p. m., was a very enjoyable part of the day, with about 130 people gathered about the tables. This dinner was at Horticultural Hall, as was also the class reception and ball, which was attended by many friends of the graduates.

ST. LOUIS COLLEGE OF PHARMACY.

The Twenty-ninth Annual Commencement exercises of the St. Louis College of Pharmacy were held on the evening of May 20th, at the Sheldon Memorial Auditorium, in St. Louis. The Hon. Charles Nagel delivered

the valedictory address on behalf of the faculty.

The candidates for the degree of Graduate in Pharmacy and Bachelor of Pharmacy were introduced by the Dean, Professor H. M. Whelpley, and those for the degree of Pharmaceutical Chemist by Professor Charles E. Caspari. The following were awarded degrees:

Graduate in Pharmacy — Monte Earl Barnes, Lydia Frankie Batdorf, Frantz Frederick Berg, Edgar Van Bratton, Ph. B. '08, Louis Edward Brown, Coke B. Browning, Hillard D. Carlos, Jr., Thomas Bowden Chambers, George William Collins, Ph. B. '10, William Daniel Curran, Charles Raymond Davis, Clifford H. Fischer, Walter Freudenberg, Adam Guthrie, Jr., Ph. B. '12, Oliver O. Hedrick, Frank John Helms, Ernest Barthol Hoehn, John Atchison Hudson, Elmer Gaynor Joseph, Henry Adam Karber, Frank Kincaid, Louis Oscar Kloeckner, William Krummenacher, Charles Lasersohn, Junius Blanton Linn, Willard McKee Lyons, William Paul Massock, Albert Henry Mayerhoffer, William Leslie McQueary, Fred George Messerschmidt, Edwin Archer Monell, Albert William Mueller, Arthur August Overman, Cressie Delahae Panhorst, Cecil Robert Parks, Alexander Pearlstone, Virgil Earl Pirtle, Benjamin James Pope, David S. Ralston, Ph. B. '12, Walter Augustus Reese, Ph. B. '12, Edwin Jerome Rhein, Kenneth Parke Riley, Edwin Louis Schroeder, Verner Franklin Smith, Gilbert Spieldoch, Mrs. John Esther S'Renco, Hans Alwin Weber, Odus Pharr Wilkinson, Lee Howard Witty, Claud Oakley Wright.

Bachelor of Pharmacy—William Francis Brennan, Hull Wesley Butler, William Henry Duckworth, Arthur Henry William Charles Kloepper, Charles F. Lanwermyer, Chester William Lieder, Albert Leo Spaedy.

Pharmaceutical Chemist—David S. Ralston.

The awards for honors were as follows:

Senior Class Scholarships and Prizes.

The Alumni Prize, a gold medal, conferred upon a candidate for the degree of Graduate in Pharmacy for the best examination in all branches, is won by Frantz Frederick Berg.

The College Silver Medal conferred upon a candidate for the degree of Graduate in

Pharmacy for high averages in all branches, is won by Frank John Helms.

The recommendation for membership in the American Pharmaceutical Association, with dues for 1914 given by the college, is awarded to Junius Blanton Linn.

Honorable mention: Graduate in Pharmacy Class—Miss Cressie Delahae Panhorst, Miss Lydia Frankie Batdorf, Fred George Messerschmidt, Alexander Pearlstone, Walter Freudenberg, William Paul Massock.

Honorable mention: Bachelor of Pharmacy Class—William Henry Duckworth.

Junior Class Scholarships and Prizes.

The Edward Mallinckrodt Scholarship for 1914-15, Joseph Frey.

The Meyer Brother Scholarship for 1914-15, Glenn Adrian Burkhart.

The J. S. Merrell Scholarship for 1914-15, Roland Henry Kraege.

The Alumni Prize, some Standard Work on the subject of Pharmacy, or allied branches, Herbert W. Bixon.

Honorable mention: Junior class—Joseph Frank Evans, Sam Honigberg, Philip Ludger Chiles.

KANSAS CITY COLLEGE OF PHARMACY.

The Twenty-ninth Annual Commencement of this institution was held on Thursday evening, May 7th, at Spalding's Auditorium. The members of the graduating class were: Charles A. Bailey, Paul H. Blinn, Ralph E. Foster, Anna Freesman, James J. Flynn, Roscoe M. Hutchinson, Cristobal Martinez, W. Frank Malson, Clyde W. Moll, W. R. McDanel, Walter F. Probst, Ray O. Piper, George A. Walkup, Sumner R. Williams, Harry E. Price, Earl Dewees, George E. Seidler.

The Junior Medal was awarded to Giles E. Wickmire, of Larned, Kansas, and honorable mention was given to Harry Kelly and Thos. D. Evilsizes, of Kansas City.

The Alumni Medal for Chemistry was awarded to Ralph E. Foster, of Perry, Oklahoma, who also received the College Medal for highest general average in all courses. James J. Flynn and Roscoe M. Hutchinson received honorable mention.

The annual ball given by the Alumni Association to the graduating class occurred on the evening of May 5th, at Drexel Hall.

Mr. and Mrs. D. Victory Whitney were members of the Reception Committee. Professor Whitney is Director of Pharmaceutical

Laboratories and Professor of Pharmacy, and Mrs. Whitney is Professor of Botany and Pharmacognosy at the College.

NEW JERSEY PH. A.

The New Jersey State Association will hold its annual meeting on the 16th, 17th, 18th and 19th instant, at the New Hotel Breslin, Lake Hopatcong, and a most pleasurable and profitable meeting will undoubtedly result from the very comprehensive scope of the program outlined. This association is one of those which seems to have successfully solved the question of combining properly the entertainment features with those involving solid instruction, profitable to every member. The list of queries proposed as subjects for papers should be most fruitful of results in the way of information of weighty import, not alone to the members of this association, but also to the pharmaceutical profession at large.

The Pennsylvania Pharmaceutical Association will hold its annual meeting at Buena Vista Spring Hotel on June 23-24-25. From the very interesting list of subjects for queries, sent to the members, some papers of exceeding interest to the trade are to be looked for.

The Massachusetts State Pharmaceutical Association will convene at the New Ocean House, Swampscott, for the thirty-third annual meeting on June 16-17-18. The program promises a very interesting and pleasurable meeting.

WOMEN'S PHAR. ASSOCIATION PACIFIC COAST.

The regular monthly meeting was held April 24, 1914, in the Assembly Hall, San Francisco. Mrs. R. E. White, the President, presided.

The roll call showed a large attendance. Discussions were held on Isotonic Salt Solutions, the preparation of Extract of Malt and Cod-Liver Oil, Methods of preparing Ichthyol Capsules, Iodothyrene and Thyroidectin.

A communication was received from Miss Clarissa Roehr, Secretary *pro tempore* of the San Francisco Branch of the A. Ph. A., inviting the participation of the members in the next meeting of that Branch.

Miss Mabel Dolcini read a paper on Ozone, and Mrs. F. F. Rajotte presented a paper on Boils. The discussion of the evening was on The Card-Index for Stock, and Miss Nelson,

Mrs. White, Miss Dolcini and Dr. Winslow spoke upon that question.

ATLANTA WOMAN PHARMACIST CLUB.

The Atlanta Woman Pharmacist Club met in the library of the Southern College of Pharmacy, April 24th, 1914, for the purpose of forming a permanent organization.

Dr. R. C. Hood, Dean of the Southern College of Pharmacy, acted as temporary chairman.

The following list of officers were elected: Miss Margaret Kimmel, President; Mrs. G. E. Matthews, Secretary, and Miss Bertha Davis, Treasurer.

It was voted that the club retain the title "Atlanta Woman Pharmacist Club."

The purposes of the club are to keep its members informed of the advance of the pharmaceutical profession, to uplift woman's position in the pharmaceutical world, and to meet socially for the entertainment of its members and guests.

Miss Bowie read an interesting paper entitled "Woman in Pharmacy," and it was decided that at each meeting the members would read papers, tell of the interesting things met with in their work, and make suggestions for the good of the club and its members.

The matter of fees being brought before the meeting, it was voted that each member be assessed an initiation fee of 25 cents and regular dues of 20 cents per month.

It was also voted that the regular meeting of the club be held on the third Friday of each month.

After the business meeting, refreshments were served.

The meeting then adjourned to meet Friday, May 15th, 1914.

Mrs. G. E. MATTHEWS, Secretary.

KANSAS PHARMACEUTICAL ASSOCIATION.

The Kansas Pharmaceutical Association met at Hutchinson on May 12, 13 and 14. There was a very gratifying attendance of the members, notwithstanding that the meeting-place was far from all the large cities and in the less-densely populated western portion of the state.

The address of President C. C. Reed was replete with timely suggestions of benefit to the members of the profession. Secretary

D. v. Reisen reported a large amount of work accomplished in many ways for the relief of vexatious conditions affecting the trade, and an increase of membership in the Association,—seventy-nine members being added during the past year, making a total roll of nearly six hundred and fifty.

The Association voted to continue its affiliation with the N. A. R. D. and also that, in the future, members of the Kansas State Board of Pharmacy shall not be eligible to serve more than two successive terms.

The special guest of the occasion was Mr. Thomas H. Potts, the National Secretary of the N. A. R. D. To the great regret of all present Mr. Potts was unable to take part in all the proceedings of the meeting, owing to a sudden illness, from which he did not entirely recover until after the adjournment of the meeting.

Dr. J. B. Wood, representative of P. D. and Co., read a very interesting paper on "Biological Products," which was of much interest to the members, and Mr. R. E. Bell, of Frederick Stearns & Co., contributed a paper upon "Cooperation," from which many of the members derived a number of ideas which will undoubtedly result in profit to them.

A special commemorative meeting was held by the Association in memory of Mr. Charles M. Becker, late of Ottawa. Mr. Becker served for many years as a member of the Kansas Board of Pharmacy. Many of the members paid a fitting tribute to his name and memory.

The following board of officers was elected: President, Walter J. Bangs; First V. P., J. W. Giesburg; Second V. P., E. E. Bloom; Secretary, D. v. Riesen; Treasurer; John Schmitter.

The Association were the guests of the Traveling Men's Association at a banquet given at the Bissante Hotel. Plates were laid for three hundred guests and the affair reflected much credit on the hosts.

The ladies were charmingly entertained during the days of the convention by a musicale and women's reception and a grand ball at the Elks' Club, and every minute of their stay in Hutchinson was made enjoyable.

Mrs. C. E. Wherrett was elected President, and Mrs. N. C. Edelblute, Secretary of the Ladies' Auxiliary.

It was voted to hold the next meeting at Wichita, May 11-12-13, 1915.

Proceedings of the Local Branches

"All papers presented to the Association and its branches shall become the property of the Association, with the understanding that they are not to be published in any other publication than those of the Association, except by consent of the Committee on Publication."—By-Laws, Chapter X, Art. III.

Reports of the meetings of the Local Branches should be mailed to the Acting Editor on the day following the meeting, if possible. Minutes should be *plainly* written, or typewritten, with wide spaces between the lines. Care should be taken to give proper names correctly, and manuscript should be signed by the reporter.

<>

CHICAGO.

The Chicago Branch of the A. Ph. A. was honored at its April meeting, the evening of the twenty-first, with an address by Professor John Uri Lloyd of Cincinnati. Professor Lloyd's subject, "The Evolution of American Materia Medica," led to many reminiscences and his talk was very earnestly received by the audience.

Secretary Gathercoal introduced the new A. Ph. A. button, samples of which had been received from Treasurer Whelpley and orders were taken for twenty of the buttons. They were voted very neat in design and excellent in finish.

The May meeting will be devoted to a criticism favorable and unfavorable of the changes in the monographs of galenicals for the new pharmacopœia as recently published by the Revision Committee. Several pharmacists, members of the Branch, led by I. A. Becker, pharmacist at Michael Reese Hospital, are preparing criticisms to be presented at this meeting.

E. N. GATHERCOAL, Secretary.

<>

CITY OF WASHINGTON.

The April meeting was held on the sixteenth of that month at the National College of Pharmacy.

The director of the National Vaccine and Antitoxin Institute of Washington, D. C., Dr. J. R. Stewart, described to the large number of members and guests, and to the entire senior class of the National Col-

lege of Pharmacy, present by special invitation, in a most interesting and detailed fashion, the origin and development, manufacture, characteristics, and peculiarities of each vaccine and antitoxin now in practical use, and outlined the character of experimental work now being conducted to increase the scope and efficacy of this form of medication. He supplemented his address with exhibits showing antitoxins in various stages of manufacture and with demonstrations of the uses of various types of syringes.¹ Following his address, he answered all questions propounded to him concerning this line.

When he took his seat, he was given a rousing vote of thanks.

The May meeting was postponed to June 6, 1914, when the branch will visit the Department of Agriculture Drug Farms, opposite the Arlington National Cemetery, in Virginia, at 1:30 p. m. At this meeting, Dr. Stotsenberg, who is in charge of the farms, will, after showing the members around, give a talk on drug plant culture, fake money-making schemes involving such culture, and a number of other subjects interesting to the retail druggist and to the general public.

HENRY B. FLOYD, Secretary.

<>

DENVER.

At the meeting in March, Mr. A. W. Clark read the following paper on "Trade Conditions."

Mr. Clark prefaced the delivery of his paper by reading a clipping from a trade journal which strongly advised that a proprietor should "stand-in" with his clerks. The clipping stated that it was quite as commendable an aspiration to desire to "stand-in" with clerks, as it was to wish to "stand-in" with the public, and that a man who only hires clerks to do the small things in his business will always have a small business.

Mr. Clark, continuing, said:

I shall not attempt in this paper to make an elaborate analysis of trade conditions, or to give the reasons for them, for, as the viewpoint of every business man is obtained, as a rule, from the front-door of his own store, every one has reasons of his own for their existence, and his remedy for those

¹Dr. Stewart's paper appears in another portion of this issue.

conditions which need reformation. My only purpose in reading this paper is to attempt to entertain you; to assist you in passing a pleasant hour in a social way, and to offer to you, only in a general way, a few suggestions for your consideration. Our Branch meetings have been a source of pleasure to me and I presume every member should do his part toward making them of enjoyment and profit to all the members, and it is with that purpose and desire that I offer these suggestions for your consideration.

It seems to be generally conceded that trade is not what it should be and does not amount in volume or show sufficient profit to justify our present expensive methods of securing it.

How may we better these conditions?

Reducing the expense account naturally comes up for consideration first, but this does not always bring the desired result, especially if it is done at the expense of the quality of service furnished.

To cover the field of local drugdom and furnish actual statistics would take much time, besides I am at a loss to know just where to go for the information and facts that will show the real conditions.

The jobber and the banker might furnish some very interesting material, but to make matter of this nature public would be a rank violation of business ethics.

I here suggest as a general underlying principle to be adopted by the man of limited financial resources when starting in business, that he consult and advise frequently with his jobber and banker, making correct statements to them regarding his resources and as his business may progress, of his sales-credits, etc., and that he consult with them both before contracting any considerable debt or signing of binding contracts, etc.

By doing this he will have time to consider the thing himself that he proposes to do, and he will have the advice of the man that has, as a rule, a much broader business experience than he himself possesses.

I believe that many business men would gain very materially by adopting this rule, men that may have been in business for years as well as the young man just nosing his way in.

It is not necessary to suggest this policy to experienced men for it is presumed that they know the importance of it and have benefited by it.

It seems to be the opinion of some that the business of an attorney is to get their clients out of trouble, but as a matter of fact the real business of an attorney is to keep them from getting in, therefore it is well to be advised before acting, and to whom may we go for that advice more freely than to the ones that prosper as we prosper, or who suffer loss should we fail, viz.: the jobber and the banker.

If the above suggestion had been adopted by all our local business men, conditions in Denver, I venture to assert, might be far better than they are today.

As we look over the local field, seemingly, we find too many persons trying to operate or to conduct drug stores.

This statement seems to be substantiated fully if we may judge their success by their financial rating.

Had some of these advised with their jobber or banker I do not believe they would have gone into business.

This condition of an excess number of stores seems to be found more frequently in the city than in the country.

"Can we find any remedy for it that is practical?" is a question often asked.

The elimination of the less competent and the survival of the stronger and better qualified is the usual rule that maintains, and this will in time undoubtedly apply here—it is gradually working out that way. It may be possible to hasten this elimination process by consolidating several stores in one, to be operated under the combined management of the several now independent proprietors.

For instance, when by close application and long hours several stores are operating and each supporting in a limited way, one person, would it not be possible to consolidate several of these stores, giving one three-man store in place of three stores of one man each, and giving better working hours, a fair remuneration and better opportunity to enjoy some of the blessings of our God-given sunshine and the glorious mountain scenery that lie at our very doors,—scenery and sunshine and pure air, not excelled in any part of the known world, all this, without price and with but very little effort, may be enjoyed in Colorado.

Then again, another remedy might be for the proprietor to just simply forget that his store is called a drug store, just forget the drug end of the term and operate a good

store, a little neighborhood store, with a notice on the door, "Open at 8 a. m., close at 6 p. m.; no Sunday business."

Considering the curtailing of expense and satisfaction that would be derived, our proprietor might find himself as well-off financially at the end of the year, as he does now working under present conditions.

This is not intended to reflect on the small man simply because he is operating a small store, but is offered just as a suggestion to fill in, and in all seriousness, the fact remains, that it is almost impossible to do any considerable amount of prescription work in any considerable number of stores in Denver, for the reason prescriptions are not written in proportionate number to the number of drug stores. The wide range in the number of articles possible for the physician to prescribe, and the great number of physicians writing prescriptions in a city the size of Denver make it impossible for the majority of stores to stock all of the items prescribed, that are more or less in daily demand.

To put it another way, comparatively, there are only a few druggists that are justified (considering the limited demand) in stocking all the remedies that are in general use.

The consolidation of several stores in each district, would remedy the conditions just stated and if this be done in all parts of the city, more complete stocks might be carried at a profit where now they show a loss. The people would be better served and a waste, that is now almost criminal from an economic viewpoint, would be corrected and saved.

Will this condition ever be remedied by the American people? For this condition, being true of Denver, applies to other cities in this country.

Making a low price on drugs does not bring more business. Generally speaking, people do not buy more drugs because the drugs are cheap or sold at a low price, that is, in the same way one might buy clothing or merchandise. A man might buy two shirts instead of one, if the price be attractive, but we do not presume he would take two doses of castor oil simply because he could get the two for the price of one.

As a rule the doctor that gives his services for a dollar, does not have as many patients as the two or five-dollar man. After all, it

is not so much the price in either case as it is the man.

If the price of drugs be reduced one-half in the city of Denver, we do not presume (barring the joy-producing variety) the amount consumed would be very materially increased. The personality of the man is reflected in his establishment, be it large or small, and is a special factor in making for success or failure. This applies to all mercantile houses, it extends to railroad management and very much so in the operating of a drug store or pharmacy.

To our methods of doing business we might apply the old saying: "It is not what you do but how you do it."

Then again, it is well to watch the successful man, the man that succeeds. Contact with better men, generally is of benefit to the man that may not be quite so good. We all have much to learn in this game called "trade."

There is an evolution going on in drugdom, in Denver, and in the nation, and no man can stay it or turn the tide very materially. We, as individuals, may assist in the moulding or shaping of it, but we cannot expect to have everything our way.

Large financial interests are taking over numbers of drug stores in the thickly populated centers, seemingly for the purpose of securing an outlet for certain lines of goods.

It does not seem to be their purpose to elevate pharmacy, or the pharmacist, in the way many have hoped for, but, seemingly, their purpose is to commercialize pharmacy, and incidentally the pharmacist.

These conditions, fortunately, have not been as pronounced in Denver as in some other cities.

We seem to have entirely different local conditions to contend with—different from Eastern and different from Western in many respects.

If Denver were a larger city, we might expect them to prevail here.

In the years that have passed, we, in Denver, have prospered to a greater degree than some of our less fortunate brethren in the East. We have had coöperation of the jobber and the retailer, something that has not existed in many Eastern cities, of any considerable size.

Just what the future has in store for us, no

man knows, but let us remember the principles which have stood for prosperity. Do not turn from the old to the new, without considering what is to be gained by the turning.

It seems that much might be gained by legislation and enforcement of present laws—laws that are supposed to protect the people and benefit us as well.

If our laws are unjust and do not correct the evils that exist, let us try and amend the same.

Our Board of Pharmacy should be of service to us in regulating the pharmacy end of our business. Let us work with them to bring about this result. Surely the raising of requirements for qualification, with enforcement of the law, will eventually help to some extent, and at the same time guarantee to the people better and more intelligent drug store service.

Our State Board of Health should work advantageously with us in correcting many evils, that some think now exist.

Every druggist should be willing to assist them in enforcing the law.

The act of March 3, 1907, regulating the sale of food and drugs in Colorado, is in the main good, and, having a standard for drugs, we have an advantage over the grocery man, who really has no standard for many food products.

As business men, we should not feel that we must depend upon the law to protect us, over and above any other class of citizens. We should first learn to protect ourselves. Being amenable to the law and contributing to its support, we have the right to expect the benefit that may be derived from an intelligent enforcement of it.

If our fellow druggists could but realize the benefit gained by social contact in our Branch meetings—even in the way of trade betterment—we would soon have to secure a larger meeting room.

While a talk of this nature may touch upon only a few of the many viewpoints of trade, it may sandwich in with some of the more scientific and interesting ones, for pharmacy and merchandising seem to go hand in hand, more and more, and the pharmacy of the future may be more commercialized than it is today, if the signs of the times are correctly interpreted.

SAINT LOUIS.

The Saint Louis Branch met in regular session at the College of Pharmacy on Friday evening, April 17th, with President Wilkerson presiding. The minutes of the previous meeting were approved as read.

The Chair then briefly outlined the talk he gave before the Saint Louis Pharmaceutical Society, with the view of uniting that Association with the A. Ph. A. Branch. After some discussion, a motion was made and carried, that a committee be appointed to confer with a committee of the Society to ascertain the feasibility of uniting the two associations. The Chair appointed on that committee, Messrs. Mackelden, Buehler and Bierman.

The subject for discussion was, "Shorter Names and Synonyms for some U. S. P. and N. F. Preparations." Mr. E. A. Sennewald cited a list of U. S. P. preparations which in his opinion should have shorter names or synonyms. Professor Good read a list of synonyms and shorter names that have been presented to the revision committee for some U. S. P. preparations.

The following motion received unanimous indorsement:

Resolved, "That the use of coined names in the United States Pharmacopœia, should be discouraged except those applied to well known products which are no longer protected by patent or proprietary rights."

It was further moved and carried that a copy of this motion be sent to Professor Joseph P. Remington, Chairman of the Revision Committee.

Mr. Mackelden brought up the subject of summer meetings, stating that these outings help to keep up interest in the Branch. A motion was adopted that the President appoint a committee to arrange for summer outings, and Messrs. Mackelden, Hoester and Kring were appointed as that committee.

JULIUS C. HOESTER, Secretary.

PITTSBURGH.

At the May meeting much valuable instruction was given concerning the use of collapsible tubes for the dispensing of ointments, by Dr. F. J. Blumenschein. In opening the subject, the doctor said, "The trend of the times is toward cleanliness, and this trend should find the pharmacist leading the procession. One of the ways by which he can keep to the front is in the use of clean and progressive methods in compounding and dis-

pensings. While most of the pharmaceuticals are being standardized, and methods for improvement in manufacturing and marketing are being proposed, the ointments and allied products are being neglected. Ointments are dispensed in all kinds of containers,—bottles, tin and wood boxes, porcelain and glass jars of various colors,—without a thought as to whether the preparation is affected by light, air, moisture or the container itself. Collapsible tubes for prescription work should be made of pure (block) tin. This should be insisted upon, as they are often made of alloys of lead and other injurious metals. The advantages of collapsible tubes are many. First, the patient can use the last portion of the ointment, with the knowledge that it is just as free from contamination as the first portion, and, second, the dispenser is not required to handle a returned container, from which he might contract anything from simple itch to smallpox. A canvass of the oculists, to learn why they so frequently prescribe ready prepared ointments in tubes, revealed the fact that, while they prefer freshly prepared ointments, they are willing to prescribe something which, while not as good, yet always carries the assurance of being clean. Of course, all ointments cannot, owing to their composition, be dispensed in metal tubes, yet a great many may be so dispensed. The cost is but slightly greater, and they require a little more time to prepare, but these disadvantages are greatly offset by the fact that a better price can be demanded and increased prestige gained by doing things right.

"Ointments which have been fused, or that have to be sterilized, can be readily poured into the tube; others can be placed in waxed paper and rolled into a cylinder in the hand, then placed in the tube and by partly closing the paper, it can be drawn out, leaving the ointment in the tube."

The subject of "The Sale of Heroin; Its Legal and Moral Status," was discussed from every viewpoint, by Drs. J. A. Koch, G. W. Kutscher, Louis Emanuel, President Andrew Campbell and B. E. Pritchard. A motion was unanimously adopted, commending the Harrison Anti-Narcotic Bill now pending in the Senate, and instructing the Secretary to convey to Senators Penrose and Oliver the request of the Pittsburgh Branch, that they urge the immediate passage of the measure in the interests of humanity.

B. E. PRITCHARD, Secretary.

NASHVILLE.

The Nashville Branch of the A. Ph. A. held one of the most interesting meetings of the year, at Furman Hall, Vanderbilt University, May 14, with Dr. J. O. Burge in the chair.

Dr. J. M. Rogoff made a preliminary report of some pharmacological experiments he has been making, to determine the amount of deterioration of aqueous alkaloidal solutions. His work, so far, has been confined to that upon solutions of morphine, atropine, pilocarpine and strychnine, testing them upon cats and frogs, and his results indicate a gradual deterioration of these solutions with age. His final results will be reported to the Scientific Section of the A. Ph. A., at the Detroit meeting. A paper entitled "Board of Pharmacy Questions," was read by W. R. White, and discussed by Messrs. Ira B. Clark, M. E. Hutton, Dr. E. A. Ruddiman and Dr. J. M. Rogoff. The subject for the evening, "Shorter Hours," was then taken up for discussion.

The Secretary read the results obtained, by sending out 200 return cards. These showed that 84 percent favored shorter hours, and that 92 percent favored closing certain hours on Sunday, but there was much divergence of opinion as to the best way of accomplishing the reform. After remarks by various members, the Branch adjourned until September.

W. R. WHITE, Secretary.

PHILADELPHIA.

The regular monthly meeting was held at the Drug Club, on Tuesday evening, May 5. After hearing the reports of the officers and of the various committees, it was decided, upon motion by Mr. W. L. Cliffe, to recommend to the American Pharmaceutical Association that the proposed national headquarters be located in Philadelphia, and the committee was directed to communicate with the proper officials of the parent body, and advise them of the advantages which Philadelphia possesses for the proposed headquarters.

A vote of thanks to the Philadelphia Drug Club for the use of its rooms for meeting purposes during the past year, was proposed and unanimously carried.

The program of the evening consisted of a discussion of the Harrison Bill and other legislative questions of state importance. Professor Charles H. LaWall presented a

paper entitled "Some Pennsylvania State Laws, Other than Pharmacy Laws, Which affect the Retail Druggist."

Secretary R. P. Fischelis presented a brief review of the Harrison Bill and amendments, and read communications from Messrs. Samuel L. Hilton, Martin I. Wilbert, A. Hopkins Stewart and F. H. Freericks, on the same subject.

C. Mahlon Kline spoke at length on the proposed anti-narcotic legislation, telling of the work of the National Drug Trade Conference and of the various state laws which propose to regulate the traffic in narcotic drugs. Mr. Samuel C. Henry gave the views of the N. A. R. D. on this question, and also spoke favorably on the Nelson Amendment now before the Senate.

At the conclusion of the discussion, it was voted that the Philadelphia Branch go on record as approving the purpose of the Harrison Bill, and as favoring the Nelson Amendment. This being the last meeting before the summer recess, adjournment was taken until October.

ROBERT P. FISCHELIS, Secretary.

NEW YORK.

The April meeting of the New York Branch of the American Pharmaceutical Association was held at the College of Pharmacy on the 13th, with Professor Army in the chair, and with Louis Berger acting as Secretary, in the absence of Secretary McCartney.

Treasurer Weinstein reported a balance of \$98.87 in the treasury. Chairman Anderson, of the Legislative Committee, informed the Branch regarding conditions at Albany, reporting the passage of the Walters-Seelye Bill placing the regulation of the hours of labor for drug clerks back under the pharmacy act, and of the Boylan anti-narcotic bill. Dr. Anderson also spoke of the amendment proposed to the Harrison Bill, relative to keeping a record, by physicians, of narcotics dispensed by them, and of the opposition created thereby. The progress of the Stevens price-maintenance bill was reported, as well as an announcement of the approaching meeting in interest of the bill.

Dr. George C. Diekman, Chairman of the Committee on the Progress of Pharmacy, read an interesting report, which discussed for the most part the work of the German Apothecaries Society, notably at the Uni-

versities of Berlin and Goettingen, on the examination and exposure of questionable proprietary medicines. The following items were dealt with:

Salicol—a tablet marketed by Dr. M. Weitemeyer, of Erfurt, said to contain acetosalicylic and citro-salicylic acids, which upon investigation of Von C. Mannich and L. Schwedes, was found to consist of acetosalicylic acid. The claim made that the tablet contained in addition to the above, citro-salicylic acid, was pointed out to be false and misleading.

C. Mannich and G. Leemhuis, in *Apotheker Zeitung*, No. 19, 1914, page 194, report on the examination of codeine tablets, as follows:

The investigation was undertaken in response to the request of the German Apothecaries Society. The tablets were claimed to contain 0.05 gm. of codeine phosphate each, and had been obtained by a physician through agency of a mail-order concern. Upon examination the tablets were found to be uneven in size and thickness. This variation was very material.

In weight these tablets varied between 0.16 and 0.25 gm. For purpose of ascertaining the codeine content, the following procedure was employed. Ten tablets, weighing 2.07 gm., were treated with 10 gm. of diluted solution of sodium hydroxide, until they disintegrated. The mixture was then shaken out with 100 cc. of ether. Forty cc. of the ether containing the basic codeine were allowed to vaporize at low temperature, and the residue (codeine) dried at 100° C. and weighed.

The residue thus obtained was found to weigh 0.1829 gm. for the 10 tablets, which equals 0.01829 gm. for each tablet. As a control, a determination of the phosphoric acid, by the ammonium molybdate method, was carried out. The amount of phosphoric acid found corresponded closely to the amount of codeine found. Calculation shows that each tablet contained 0.015 gm. of codeine phosphate, instead of 0.05 as claimed.

It would therefore seem that the quantity of codeine phosphate was mis-stated, and that each tablet contained only about one-third of the quantity claimed.

M. Pawlewskis' Eye-Water, which was claimed to strengthen weak eyes, cure cataract and glaucoma, heal inflamed eyelids, granulated eyelids, cure scurvy and bleeding of the gums, was found to contain zinc sul-

phate 1.25 percent; sodium chloride 1.32 percent; water q. s., and it was pointed out that extravagant claims had been made for an old and well-known preparation which is being marketed under a new name.

Schumacher's Cell Regenerator, No. 13, was reported in *Apotheker Zeitung*, No. 18, 1914, page 186, by C. Mannich and S. Kroll, as consisting entirely of sugar of milk.

A physiological determination of the value of certain digitalis preparations was made by Von Dr. Anton Lehnert, Bad Duerkheim; and Professor Oswald Loeb, Goettingen:

The authors examined a number of well-known digitalis preparations, with a view to establishing their therapeutic value in a physiological way. They employed the method of Frankel-Gottlieb, comparing the results found, in the examination of the preparations, with the results found upon using an infusion of digitalis, prepared from titrated digitalis leaves obtained from the firm of Caesar & Loretz.

The folia digitalis titrata, of Caesar & Loretz, was found to show a constant therapeutic value when tested from year to year, which the authors state to be as follows: Each 0.1 gm. of the substance is the equivalent of 5 Gottlieb units.

A Gottlieb unit is designated, the smallest quantity of substance required to produce a systolic cessation of heart-action in a frog, weighing from 29-32 grams, with certainty, within 30 minutes.

Digitalis dialysata Golaz: The preparations intended for intravenous injection, showed only from 16 to 40 percent of their claimed value. The preparations intended for internal medication were found to correspond in their declared value.

Digifolin: This preparation is placed on the market, both in solution and tablet form. Its activity conformed closely to the claimed values, and the contents of the packages were found unchanged after 11 months.

The authors claim that their results have been confirmed by other investigators.

An exhaustive report on concentrated ipecac infusions was referred to as having appeared in *Phar. Zentralhalle*, 1914, No. 11, page 249, the authors of which were Von C. Mannich and W. Duehr, and the conclusions reached were as follows:

(1) That a properly prepared infusion of ipecac contains only about three-fourths of the alkaloidal value of the drug employed.

(2) That an infusion prepared with the aid of a concentrated infusion (1:20) formula of Dieterich, contains only two-thirds the quantity of alkaloid, as will be found in a properly and freshly prepared infusion.

(3) That alkalis should under no circumstances be added. This is sometimes done in order to impart a deeper color to the product.

(4) That the concentrated preparations of the market are unreliable, and that they always contain a much lesser quantity of alkaloid than an infusion properly made.

The report was discussed by Messrs. Raubenheimer, Latham and Weinstein.

Dr. Diner called attention to the approaching meeting of the State Medical Society, to be held at the Hotel Astor, and moved that the Branch send delegates. The motion was carried.

Dr. J. L. Mayer then read the paper of the evening, entitled "The Standardization of Volumetric Acid and Alkali Solutions."*

The paper brought out an interesting discussion, participated in by Messrs. Schmidt, Roemer, Raubenheimer, Niece and Arny.

LOUIS BERGER, Acting Sec'y.

SAN FRANCISCO.

Thursday evening, May 12th, the San Francisco Branch of the American Pharmaceutical Association was permanently organized. The following officers were elected: President, Dr. Albert Schneider; First Vice-President, Jennie M. White; Second Vice-President, Arthur Reum; Secretary-Treasurer, Clarissa M. Roehr; Council Member, Dr. A. Schneider.

Communications were received from Mr. J. W. England and Dr. F. E. Stewart. Mr. England, as Secretary of the Council, conveyed the unanimous approval of that body to the organization of the San Francisco Branch. Dr. Stewart congratulated the members and wished the future success of the Branch.

The following program was presented during the evening:

The United States Pharmacopœia:—

"From the Standpoint of the Chemist," by Arthur Reum.

"From the Standpoint of the Pharmacist," by Clarissa M. Roehr.

*This paper appeared in full in the last issue of the JOURNAL.

"From the Standpoint of the Pharmacognosist," by Dr. A. Schneider.

"The Italian Pharmacopœia," by Dr. A. S. Musante.

"The British Pharmacopœia," by Miss M. Low and Mrs. R. E. White.

"The Homeopathic Pharmacopœia," by Mr. Lengfeld.

Discussions on the German Pharmacopœia and on the French Codex were postponed to a later date.

The next meeting will be held on June 9th in the office of the Pacific Pharmacist. The members will discuss a paper on "Some Points for the Pharmacist Regarding the Products Used in Organo-therapy," by Dr. John Zieg.

CLARISSA M. ROEHR, Secretary.

CINCINNATI.

The first annual meeting of the Cincinnati Branch, A. Ph. A., was held at Lloyd's Library, May 12, with Vice-President Prof. Theo. D. Wetterstroem in the chair.

The Treasurer, Mr. F. S. Kobbe, presented his annual report, which was accepted, and a vote of thanks was tendered him for his efficient service.

The Secretary followed with a complete record, covering the work of the first year's life of the Branch. The report was accepted with a recommendation to preserve the original minute book and its insertions.

Mr. Edward Voss, Jr., Chairman of the Committee on Membership, reported for that committee.

Prof. C. T. P. Fennel, Chairman of the Committee on Pharmaceutical Progress, made a report and, being the accredited member of this Branch to the Council of the parent body, he gave information regarding the work accomplished by the Council. A resolution of regret regarding the resignation of Prof. J. H. Beal as General Secretary, was passed, deploring the necessity for the retirement of one who has performed such efficient service in the cause of American Pharmacy.

The annual report of the Legislative Committee was presented by Hon. Frank H. Freericks in a very comprehensive manner, covering the different pending bills of state and national importance, such as the Duffy Anti-Narcotic Bill, the Itinerant Venders' Bill, the Stevens Bill, the Harrison Bill, the Clapp Bill and others. The report was accepted, and it

was voted that it be sent in its entirety to the JOURNAL for publication.

The presiding officer, Prof. Theo. D. Wetterstroem, read the following resolution, passed by the Agricultural Commission of Ohio, April 28, 1914:

"The Agricultural Commission of Ohio interprets the Insecticide and Fungicide Act and the Feed Stuff Act as exempting from their provisions all drugs, chemicals, etc., recognized by the U. S. P., N. F. or other recognized standards; all preparations extemporaneously prepared or compounded for customers for consumption and not for resale; all preparations for which no claims are made for insectidal or fungicidal properties, and all proprietary medicinal preparations and stock foods upon which license-fees have been paid by the manufacturers."

It was decided to incorporate this resolution in the report of the Legislative Committee.

Mr. Chas. G. Merrell made a report for the Committee on Transportation to the A. Ph. A. meeting, and was followed by the Chairman of the Nomination Committee, Mr. Edw. Voss, Jr., who presented the following ticket:

President, E. H. Thiesing; First Vice-President, F. W. Weissmann; Second Vice-President, J. F. Kutchbauch; Treasurer, Julius Greyer; Secretary, Chas. A. Apmeyer; Executive Committee, A. O. Zwick, three years; C. T. P. Fennel, two years; C. G. Merrell, one year.

The report was signed by F. S. Kobbe, Wm. L. B. Brittain and Edw. Voss, Jr., Chairman.

The report being duly accepted, the Secretary was instructed to cast one ballot for the nominees, which being done, the newly elected officers were duly installed by the presiding officer, each pledging his earnest support to the Branch, as well as to the parent body.

CHAS. A. APMEYER, Secretary.

The report of the Legislative Committee is as follows:

REPORT OF THE COMMITTEE ON LEGISLATION OF THE CINCINNATI BRANCH OF THE A. PH. A.

Mr. President and Members:

Your Committee on Legislation begs to report at this annual meeting that during the year there has been no legislation, either state or national, which is of particular con-

cern to pharmacists. There are, however, at this time two bills pending in Congress which are of very special interest, and which will be referred to herein.

The state laws of interest to the various branches of the drug trade which were enacted during the year 1913, and which came to be in force since that time, have been reported on at one of the regular monthly meetings during the year. They included the Agricultural Commission Law, the so-called Duffy Anti-Narcotic Law, an amendment to the Pure Food and Drug Law which declared a drug to be misbranded if labels bear or contain any statement, design or device regarding the curative or therapeutic effect of the article or any of the ingredients or substances contained therein, which is *false and fraudulent*, and finally the Insecticide Law. Since these laws became effective, the Agricultural Commission has taken up the duties which rested heretofore with the Board of Pharmacy and which were transferred to it. There appear to have been many prosecutions on account of the violation of various laws, particularly, however, with reference to the violation of the so-called Duffy Anti-Narcotic Law. While it is too early to express an opinion on the value of this particular work under the direction of the Agricultural Commission, there is but little doubt that the Commission will have many advantages in the proper enforcement of such laws, and consequently conditions should be correspondingly improved. The Duffy Anti-Narcotic Law and its enforcement by the Agricultural Commission has certainly resulted in numerous prosecutions and convictions, and continued determined activity in this respect is bound to be very helpful in the control of the narcotic evil. It, of course, is not possible for your committee to know the merits of the various prosecutions which have been made. In this connection, it is to be regretted that the Agricultural Commission construes the law as being inapplicable to physicians, dentists and veterinarians, at least such is reported to be the case. It is altogether impossible for your committee to understand how the Agricultural Commission would construe this law as not requiring physicians, dentists and veterinarians to write and file prescriptions when they themselves dispense the drugs in question. There seems to be no room for such strained construction under a plain reading of the Narcotic Law,

and in keeping with its terms physicians, dentists and veterinarians should be required to write and file prescriptions when they themselves dispense the drug. We at this time recommend that this matter be brought more directly to the attention of the Agricultural Commission, and that they be advised that this Branch of the American Pharmaceutical Association believes the law to be equally applicable to physicians, dentists and veterinarians who make a practice of dispensing. The Insecticide Law, the many uncalled-for provisions of which were brought to the attention of the Branch during the year, has since been attacked in a suit brought under the direction of the Ohio State Pharmaceutical Association, and particularly because of the earnest effort of Prof. Geo. B. Kauffman, the Chairman of its Council. We report with pleasure and satisfaction that the lower court has sustained the contention of the Ohio State Pharmaceutical Association, and has held the law to be unconstitutional because of discriminating features. Upon just what ground the decision of the lower court has been based, we do not yet know, because a publication of the opinion has not yet been available.

In considering state legislation generally, and its enforcement, it is of special interest to know, that an Itinerant Venders' Law of the State of Louisiana, in which the Supreme Court of said state upheld special license features and regulations to govern the sale of drugs by itinerant venders, has on error to the Supreme Court of the United States, been upheld by it. The decision of the Louisiana court, which was under review by the Supreme Court of the United States in this case, seems to be in direct conflict with a decision rendered on a similar law, by the Illinois Court of Appeals. We find, therefore, that the highest courts of two different states have come to different conclusions with reference to the constitutional limitations which govern state legislatures, and while the Supreme Court of the United States has sustained the conviction as made under the Louisiana law, it must be in mind, that the question before the Supreme Court of the United States was simply to decide whether the Louisiana law infringed upon the constitutional rights of citizens of the United States. Of necessity it had to leave to the state court the question as to whether the constitutional limitations of the state had

been infringed, and as already pointed out in this respect, there was a direct conflict in the decision as reached by the Illinois and Louisiana courts respectively. While some weight is added to the Louisiana decision, because of the affirmation of the Supreme Court of the United States, yet the more important question will still remain for independent decision by the several state courts, and the state courts, generally speaking, outside of the Southern States, would be more inclined to follow the decision of the highest court of Illinois than to follow the highest court of the State of Louisiana.

In proposed national legislation, the Harrison Anti-Narcotic Bill continues to be a center of interest on the part of the various branches of the drug trade, no doubt also on the part of the medical profession. The bill is still pending in the Senate of the United States. Fortunately, the National Drug Trade Conference has seen fit to advocate amendments to the bill as first approved by it, which are in keeping with the needs as pointed out by the Cincinnati Convention of the N. A. R. D. In fact, all of the amendments as they were advocated, have found either total or partial approval by the Drug Trade Conference, including the need for record requirement on the part of dispensing physicians, dentists and veterinarians. However, the proposal of the National Drug Trade Conference, with reference to the record requirement to be made of physicians, etc., who dispense and distribute narcotics, is not sufficiently definite and certain, and will not be particularly helpful to control the illegitimate distribution of narcotics by such persons, unless changed, so as to definitely require a record for each separate distribution, other than the administration of the drug by physicians themselves in cases of emergency. It appears that the need for such further change has been pointed out to various Senators, and we may hope somewhat that the change will still be made before the so-called Harrison Bill finally becomes a law. At any rate, it is now possible to say, that some of the much needed changes will surely be embodied in the law, and also that the discrimination as first made and proposed in favor of dispensing physicians has come very generally to be recognized as being improper and as seriously impairing the effectiveness of the intended law.

Another bill now pending in Congress

which is of particular interest to all of the various Branches of the Drug Trade is the so-called Stevens Price Maintenance Bill. It is the purpose of this bill to allow the manufacturer of trade-marked or proprietary articles to designate the price at which his products shall be sold to the trade and to the consumer. This bill is an outcome of the continued agitation for legalizing price regulation, as first commenced by the National Association of Retail Druggists. The movement and the support for such legislation has now taken on considerable force, and the public generally, as well as its representatives, are being educated on the need for it, and the advocates of price regulation have certainly made wonderful progress, so that it is now within reason to expect that such legislation will be enacted in some form within a reasonable time. The provisions of the Stevens Bill in singling out trade-marked and proprietary articles, are possibly not so complete as they should be, for there seems to be no good reason why the same rights should not be accorded the manufacturer of a patented or copyrighted article, in view of the fact that the courts have held that the owner of patented or copyrighted articles may not dictate the price at which such articles shall be sold by dealers. There is also some question as to the constitutional right of Congress to enact a law which, beyond the contract provisions, is to govern the owner of property which has come to be under the exclusive jurisdiction of the state as distinguished from interstate. In other words, it is a question, whether when property has come to the exclusive ownership of a resident of a given state he can be denied, beyond the terms of an actual contract, by an act of Congress to dispose of such property as he sees fit. The theory of the Stevens Bill in this respect seems to be based on an assumed analogy with the patent and copyright authority of Congress, and such analogy in fact does not exist. Your committee has not found time to devote special study to this feature, and is not prepared at this time to express a definite opinion with reference to it, but believes it well to call attention to the matter for general consideration. Whatever the case may be, the all-important fact is, that the progress for legalizing price regulation during the year has been most wonderful, and that the public and the legislators are becoming thoroughly im-

pressed with the need for some relief in this respect, and when the campaign of education has sufficiently progressed, there is no doubt about finding some legal and constitutional method for properly taking care of the matter.

Respectfully submitted,

WM. C. LAKAMP.

FRANK H. FREERICKS.

CHICAGO.

The Chicago Branch met for the last regular monthly meeting of the season at the University of Illinois School of Pharmacy building, the evening of May 19th, with President J. H. Wells in the chair.

Mr. Wells introduced Mr. L. A. Becker, who lead the discussion of the evening on the topic, "The Preparations of the New U. S. P." Mr. Becker made suggestions as to the improvement or correction of several formulas and tests. He criticised the tests for iron in "Aqua," stating that he found the "heavy metals test," of the present Pharmacopœia, more efficient than the proposed test for metals. He said that the proposed test for iron should not read "immediately" but should have a time limit. Iron 1-100,000 required one minute, to develop a positive reaction, 1-500,000 required $3\frac{1}{2}$ to 5 minutes, solutions of 1-1,000,000 showed the color only in 7 to 10 minutes. He pointed out in connection with "Aqua Destillata Sterilisata" and "Liquor Sodii Chloridi Physiologicus," the necessity for extreme care in sterilization, and recommended, for the latter solution, fractional sterilization, using the autoclave at 115° to 120° for 15 to 20 minutes on three successive days, or boiling for one hour on three successive days. Should the pharmacist become the purveyor of this preparation to the physician, the directions as proposed for sterilization, will lead to many disputes, for where there is infection, from either instruments, dressings, suture materials, or preparations, the physician often seeks to put the blame on any other cause rather than to ascribe bad results to his possibly faulty technique or poor judgment. For the pharmacist's protection against accusations of this nature, the process of sterilization should produce unquestionable results.

Mr. Wm. Gray followed Mr. Becker with the following suggestions:

Liquor Cresolis Comp.: Use Sapo Mollis and Cresol equal parts. Dissolve with heat.

Tinct. Iodi: Use 40 cc. of water to the liter of tincture for insuring solution of the K. I.; *Tinct. Aurantii Dulcis* and *Tinct. Limonis Cortex* Retain the present formula; oil will be lost by grating; *Tinctures in General*: There should be some form of standardized concentrated preparation of the assayed drugs, which could be diluted to make U. S. P. tinctures, for the benefit of pharmacists who cannot afford to make such tinctures with assay process for the same. The present Tincture of Nux Vomica is an example. Otherwise the entire preparation of assayed tinctures is going into the hands of the pharmaceutical manufacturer. The plan proposed would allow considerable saving both in cost of container, menstruum and freight.

A communication was received from Mr. R. E. Rhode, who commented as follows: *Aromatic waters* should be made with magnesia instead of talcum. Recently boiled water may lead to better preparations.

Solution of Magnesium Citrate should be made by the cold process, and with Spirit of Lemon, instead of the oil. The proposed process is altogether too complicated for what is practically an extemporaneous preparation and, furthermore, a volatile oil should not be added to a hot liquid. He recommends the return to the use of the name Tr. Saponis Mollis or Spir. Saponis Mollis instead of Linimentum Saponis Mollis.

In the discussion of Mr. Gray's suggestion of "concentrate" for tincture-making, Professor Clark opposed the idea, believing that a druggist using guaranteed assayed drugs, should be educated to prepare U. S. P. tinctures directly from them.

Professor Day suggested that neighborhood-druggists should club together and engage an expert to make the U. S. P. preparations in larger quantities and of standard quality.

Mr. Storer, in commenting on the preparation of Green Soap and Comp. Solution of Cresol, stated that he prepared the soap in 50-pound quantities, with careful manipulation and with not too close an adherence to the formula, and then allowed it to age for three months. From this soap he prepared the Cresol Solution and allowed it to age some months before use. Both preparations were declared to be very satisfactory.

Secretary Gathercoal read a letter from Mr. Fred Meissner, of LaPorte, Trustee of the Pharmacopœia, who stated that the pros-

pects for the new U. S. P. to be in print early this fall were very good indeed.

The annual convention of the Illinois Pharmaceutical Association at Fox Lake, June 11, 12 and 13th, was announced, and a general invitation to be present was issued.

Arrangements for the Chicago delegation to the convention at Detroit were also discussed.

The meeting adjourned until the third Tuesday in October.

E. N. GATHERCOAL, Secretary.

The Pharmacist and the Law

NEW YORK ANTI-NARCOTIC LEGISLATION.

The bill known as the Boylan bill, for the regulation of sales of chloral, opium, any of the salts, alkaloids or derivatives of opium, hypodermic syringes or needles, has become a law in the State of New York.

The bill prohibits the sale of these drugs and articles except upon the prescription of a physician, veterinarian or dentist, with the exception of preparations containing minimum quantities of such drugs. The law also provides for the keeping of records by the person prescribing any of the drugs mentioned in the bill, and also for the recording, by every dealer, of the name and the address of every person to whom such drugs or articles are sold. It also provides for the commitment to a hospital or institution of persons proven to be habitual drug-users, and for their detention therein until they are deemed to be cured of their morbid desire. It further provides for the revocation of the license of any pharmacist, physician, veterinarian, dentist or registered nurse, who may be addicted to the abuse of any habit-forming drug, or who has been convicted of violation of any of the provisions of the act, but, while in the first instance, it provides for the re-issuance of a license on the reformation of the habits of a habitual drug-user, the revocation of a license after conviction, seems to be intended to be of permanent continuance,

not subject to a revision. The full text of the bill follows:

AN ACT TO AMEND THE PUBLIC HEALTH LAW, IN RELATION TO THE SALE OF HABIT-FORMING DRUGS.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:—

Section 1. Chapter 49 of the laws of 1909, entitled "An act in relation to the public health, constituting chapter 45 of the consolidated laws," is hereby amended by adding after article 11 a new article to be article 11a thereof, to read as follows:—

ARTICLE 11a.

Habit-Forming Drugs.

Sec. 245. Sale prohibited; exception. No pharmacist, druggist or other person shall sell, have or offer for sale or give away any chloral, opium or any of its salts, alkaloids or derivatives, or any compound or preparation of any of them except upon the written prescription of a duly licensed physician, veterinarian or dentist, provided that the provisions of this article shall not apply to the sale of domestic and proprietary remedies, actually sold in good faith as medicines and not for the purpose of evading the provisions of this article, and provided further that such remedies and preparations do not contain more than two grains of opium or one-fourth grain of morphine or one-fourth grain of heroin or one grain of codeine or ten grains of chloral or their salts in one fluid ounce, or if a solid preparation, in one avoirdupois ounce, nor to plasters, liniments and ointments for external use only.

Sec. 246. Prescriptions; certificates. It shall be unlawful for any person to sell at retail or give away any of the drugs, their salts, derivatives or preparations mentioned in section 245 of this chapter, except as herein provided without first receiving a written prescription signed by a duly licensed physician, veterinarian or dentist. The prescription must contain substantially the following:—The name in full of the physician, veterinarian or dentist issuing such prescription, his office address, his office hours and telephone, and the name, age and address of the person to whom and date on which such prescription is issued. It shall be unlawful for any duly licensed physician, veterinarian or dentist to issue any such prescription containing any of the drugs, their salts, derivatives or preparations mentioned in section 245 of this chapter except after a physical examination of any person for the treatment of disease, injury or deformity. It shall be unlawful for any person to sell at retail any of the drugs or preparations of any of those mentioned in section 245 of this article without first verifying the authority of any prescription containing more than four grains of morphine, thirty grains of opium, two grains of heroin, six grains of codeine or four drams of chloral. Such veri-

fication can be made by telephone or otherwise. Such prescription so received shall be filled out at the time of receiving the same for the full quantity prescribed and no prescription so received shall be filled out more than ten days after the date which said prescription be dated. Such prescription, from which no copy shall be taken, shall be retained by the person who dispenses the same and shall be filled but once. Such prescription shall be kept on the general prescription file and given a regular consecutive number on such file. On such prescription shall be inscribed the name and address of the purchaser making such purchase and the date upon which said sale is made. Any person who sells at retail, furnishes or dispenses any of the drugs mentioned in section 245 of this chapter upon a written prescription by a duly registered physician or veterinarian or dentist shall at the time of dispensing the same, place upon the package a label or deliver therewith a certificate stating the name and address of the person selling or furnishing the same, the name and the address of the physician, veterinarian or dentist upon whose prescription such sale is made, the date of sale, and the name of the person to whom such sale is made. Any person, other than a manufacturer of any of the drugs mentioned in section 245 or a wholesale dealer in drugs or a licensed pharmacist, licensed druggist, duly registered practicing physician, licensed veterinarian or a licensed dentist, who shall possess any of the drugs mentioned in section 245 or their salts, derivatives or preparations, shall be guilty of a misdemeanor, unless said possession is authorized by the certificate described in this section.

Nothing herein contained shall be construed to prohibit the sale of any of such drugs by any manufacturing pharmacists or chemists, or wholesale or retail pharmacists, or druggists, to other manufacturing pharmacists or chemists, or wholesale or retail pharmacists, or druggists, or to hospitals, colleges, scientific or public institutions, except that such sales shall be made in the manner provided in the next succeeding section.

Sec. 247. Order blanks; filing. The State Commissioner of Health shall prepare and furnish to all Boards of Health or officers official order blanks, serially numbered in duplicate, bound in book form, with carbon or transfer paper between the duplicate pages. The said official order shall be furnished by the local Health Board or officer to any local, duly licensed physician, dentist, pharmacist, druggist or veterinarian, upon which must be written all orders for the purchase of any of the drugs enumerated in section 245 of this chapter for the use of such physician, dentist, pharmacist, druggist or veterinarian. It shall be unlawful for any person to sell, furnish or dispose to any physician, pharmacist, druggist, veterinarian or dentist any of the drugs enumerated in section 245 of this chapter without first receiving from such physician, druggist, veterinarian or dentist an official order blank as provided in this section, which offi-

cial order shall be retained by the person or corporation who sells, furnishes or dispenses any of the drugs enumerated in section 245 of this chapter, and such official order shall be kept in a separate file or book and an entry made or caused to be made on the order stating the date of sale, the name and address of the purchaser and the name of the person making such sale.

Sec. 248. Physicians, etc., to keep records. All physicians, druggists, pharmacists, veterinarians and dentists shall keep on record the name and address of each person to whom such physician, dentist or veterinarian administers or disposes in any way whatsoever any of the drugs enumerated in section 245 of this chapter, and the quantity so administered, disposed of or given away. Such record shall be preserved for five years and shall always be open for inspection by the proper authorities. Any violation of this section is hereby declared to be a misdemeanor.

Sec. 249. Hypodermic syringe; sale of; record; penalty. It is unlawful for any person to sell at retail or to furnish to any person other than a duly licensed physician, dentist or veterinarian, an instrument commonly known as a hypodermic syringe or an instrument commonly known as a hypodermic needle, without the written order of a duly licensed physician or veterinarian. Every person who disposes of or sells at retail, or furnishes or gives away to any person, either of the above instruments, upon the written order of a duly licensed physician or veterinarian, shall, before delivering the same, enter in a book kept for that purpose the date of the sale, the name and address of the purchaser, and a description of the instrument sold, disposed of, furnished or given away. Any person or persons who sell, dispose of or give away an instrument commonly known as a hypodermic syringe, or an instrument commonly known as a hypodermic needle, except in the manner prescribed in this section, shall be guilty of a misdemeanor.

Sec. 249-a. Commitment of habitual drug users; procedure; discharge. The constant use by any person of any habit-forming drug, except under the direction and consent of a duly licensed physician, is hereby declared to be dangerous to the public health. Whenever a complaint shall be made to any magistrate that any person is addicted to the use of any habit-forming drug, without the consent or direction of a duly licensed physician, such magistrate, after due notice and hearing, is satisfied that the complaint is founded and that the person is addicted to the use of a habit-forming drug, shall commit such person to a state, county or city hospital or institution licensed under the State Lunacy Commission. Whenever the chief medical officer of such institution shall certify to any magistrate that any person so committed has been sufficiently treated or give any other reason which is deemed adequate and sufficient, he may discharge the person so committed. Every person committed under the provisions of this section shall observe all the rules and regula-

tions of the institution or hospital. Any such person who wilfully violates the rules and regulations of the institution or repeatedly conducts himself in a disorderly manner may be taken before a magistrate by the order of the chief medical officer of the institution. The chief medical officer may enter a complaint against such person for disorderly conduct and the magistrate, after hearing and upon due evidence of such disorderly conduct, may commit such person for a period of not to exceed six months to any institution to which persons convicted of disorderly conduct or vagrancy may be committed, and such institution shall keep such persons separate and apart from the other inmates, provided that nothing in this section shall be construed to prohibit any person committed to any institution under its provisions from appealing to any court having jurisdiction for a review of the evidence in which this commitment was made.

Sec. 249-b. Revocation of licenses. Any license heretofore issued to any physician, dentist, veterinarian, pharmacist or registered nurse may be revoked by the proper officers or boards having power to issue licenses to any of the foregoing upon proof that the licensee is addicted to the use of any habit-forming drug or drugs after giving such licensee reasonable notice and opportunity to be heard. Whenever it shall appear after one year from date of revocation of such license that such licensee has fully recovered and is no longer an addict to any of the drugs herein prohibited, such board may grant a rehearing and in its discretion reissue the license of such licensee.

Sec. 249-c. Revocation of license after conviction. Whenever any physician, dentist, veterinarian, pharmacist or registered nurse is convicted in a court having jurisdiction of any of the violations of this article, any officer or board having power to issue licenses to any such physician, dentist, veterinarian, pharmacist or registered nurse may, after giving such licensee reasonable notice and opportunity to be heard, revoke the same.

Sec. 249-d. Penalties. Any violation of any of the provisions of this article shall be deemed a misdemeanor. Nothing contained in this article shall be construed to amend or repeal section 1746 of the penal law.

Sec. 2. This act shall take effect July 1, 1914.

FOOD INSPECTION DECISION NO. 153.
AMENDMENT TO REGULATION 9, RELATING TO
GUARANTIES BY WHOLESALERS, JOBBERS, MANUFACTURERS, AND OTHER PARTIES RESIDING IN
THE UNITED STATES TO PROTECT DEALERS FROM
PROSECUTION.

Regulation 9, of the Rules and Regulations for the enforcement of the Food and Drugs Act, June 30, 1906 (34 Stat., 768), is hereby amended, effective May 1, 1915, so as to read as follows:

REGULATION 9. GUARANTY.

(Section 9.)

(a) It having been determined that the legends "Guaranteed under the Food and Drugs Act, June 30, 1906," and "Guaranteed by (name of guarantor), under the Food and Drugs Act, June 30, 1906," borne on the labels or packages of food and drugs, accompanied by serial numbers given by the Secretary of Agriculture, are each misleading and deceptive, in that the public is induced by such legends and serial numbers to believe that the articles to which they relate have been examined and approved by the Government and that the Government guarantees that they comply with the law, the use of either legend, or any similar legend, on labels or packages should be discontinued. Inasmuch as the acceptance by the Secretary of Agriculture for filing of the guaranties of manufacturers and dealers and the giving by him of serial numbers thereto contribute to the deceptive character of legends on labels and packages, no guaranty in any form shall hereafter be filed with and no serial number shall hereafter be given to any guaranty by the Secretary of Agriculture. All guaranties now on file with the Secretary of Agriculture shall be stricken from the files, and the serial numbers assigned to such guaranties shall be canceled.

(b) The use on the label or package of any food or drug of any serial number required to be canceled by paragraph (a) of this regulation is prohibited.

(c) Any wholesaler, manufacturer, jobber, or other party residing in the United States may furnish to any dealer to whom he sells any article of food or drug a guaranty that such article is not adulterated or misbranded within the meaning of the Food and Drugs Act, June 30, 1906, as amended.

(d) Each guaranty to afford protection shall be signed by, and shall contain the name and address of, the wholesaler, manufacturer, jobber, dealer, or other party residing in the United States making the sale of the article or articles covered by it to the dealer, and shall be to the effect that such article or articles are not adulterated or misbranded within the meaning of the Federal Food and Drugs Act.

(e) Each guaranty in respect to any article or articles should be incorporated in or attached to the bill of sale, invoice, bill of lading, or other schedule, giving the names and quantities of the article or articles sold, and should not appear on the labels or packages.

(f) No dealer in food or drug products will be liable to prosecution if he can establish that the articles were sold under a guaranty given in compliance with this regulation.

W. G. McADOO,
Secretary of the Treasury.

D. F. HOUSTON,
Secretary of Agriculture.

WILLIAM C. REDFIELD,
Secretary of Commerce.

Washington, D. C., May 5, 1914.

Council Business

COUNCIL LETTER No. 17.

PHILADELPHIA, PA., April 21, 1914.

To the Members of the Council:

The following letter has been received by the Secretary of the Council from President George M. Beringer:

"I have been giving very earnest thought to Council Letter No. 16 and the communication presented therein from General Secretary and Editor James H. Beal. Since you communicated with me over the telephone the receipt of this letter of Dr. Beal, the matter has weighed very heavily upon me.

There is no question but what Dr. Beal's health must be conserved and that the Association is confronted with the necessity of relieving him at an early date from his position as Secretary and Editor. The necessity is for a most careful canvass of the field and the selection of the proper person or persons for these two offices is one of great importance to the Association. With the enlarged activities of the A. Ph. A. it is going to be exceedingly difficult for any one person to successfully fill both of these positions. It would be difficult to find in one individual all the qualifications that are required. Our previous Secretaries have set a very high mark for this position and the standing of the American Pharmaceutical Association as the exponent of American pharmacy demands that this standard shall be maintained.

Personally, I am strongly averse to the acceptance of the resignation of Dr. Beal as Editor and Secretary in the manner in which it is proposed to be done by Motion No. 28. I would like to see Dr. Beal retained as Secretary and Editor at least until the Detroit meeting. His name should be continued as the Editor and General Secretary until that time, even though his services in the interim be merely nominal. I believe that the Association can very well afford to assume this position. The work done by Dr. Beal as Secretary as well as his other work in behalf of the Association has endeared him to every member and merits at least this small recognition. The Association does not want to be left even temporarily without a Secretary, even though his connection be nominal.

If it is in order, I would move as a substitute for the two motions Nos. 28 and 29:

First—That the resignation of Dr. James H. Beal as Editor and Secretary be accepted with the sincere regret of the Council and with the understanding that such resignation shall not take effect until September 1, 1914.

Secondly—That Dr. James H. Beal be relieved of the active work of the Secretaryship and Editorship of the JOURNAL as far as possible and that he be authorized to make the best arrangements he can with Mr. Ernest C.

Marshall or other person or persons that he may select, to carry on the work of the offices of Secretary and Editor under his direction until September 1st.

This would enable Dr. Beal to make the best arrangements for his personal comfort and with the least interruption of the work of the Association."

The first substitute motion will be known as *Motion No. 30*, and the second as *Motion No. 31*.

Dr. Beal has been communicated with in reference to above, and signifies his willingness to retain the *nominal* title of Editor and General Secretary until September 1st; provided, however, that somebody can be designated as *Acting Secretary and Editor*, to whom business matters addressed to him can be referred.

J. W. ENGLAND,
Secretary of the Council.

415 N. Thirty-third Street.

COUNCIL LETTER No. 18.

PHILADELPHIA, PA., April 28, 1914.

To the Members of the Council:

Motion No. 27 (Election of Members; Applications Nos. 91 to 123 inclusive), and Motions No. 30 (Accepting Resignation of Dr. James H. Beal as Editor and General Secretary), and No. 31 (Authorizing Dr. James H. Beal to engage a person or persons to carry on the work of the offices of Editor and General Secretary until September 1; substitute motions for Motions No. 28 and No. 29), have each received a majority of affirmative votes.

The following letter has been received by the Secretary of the Council from President George M. Beringer:

"I am sending you herewith a letter received under date of April 20th from the Drug Products Co., Inc. Will you kindly include this communication in an early Council letter?"

The letter referred to is as follows:

"Mr. G. M. Beringer, President, American Pharmaceutical Association, 501 Federal St., Camden, N. J.:

Dear Mr. Beringer—Confirming recent conference with yourself, Mr. F. M. Apple, Mr. J. R. Muir and the writer, in the interest of the public welfare and the retail drug trade, we shall be pleased to co-operate with the efforts of the American Pharmaceutical Association to have the coffin-shaped Bichloride of Mercury Tablet adopted as the official design or shape for this poisonous tablet, and, to encourage and further such a

movement we will be willing to assign our exclusive rights and claims, including application for patent, to the American Pharmaceutical Association.

We also wish to confirm the writer's contention made to you in person, namely, that he regards himself as the inventor and originator of the coffin-shaped Bichloride of Mercury Tablet and can present proof that it was his intention to market such a tablet prior to the existence or incorporation of the Drug Products Co., Inc., to whom the claim has been assigned.

We direct your attention to the date of patent office letter of acknowledgment of our application for patent which is September 2, 1913, No. 787813, and also date of application for similar patent as stated in correspondence to you from The Norwich Pharmacal Company which is given as November 18, 1913, No. 801748! This in itself indicates prior right on our part. It is also a fact that our advertisement of this tablet was the first to appear in any of the papers in this country, and it is a further fact that the tablets we are marketing to-day are precisely as they have been from the beginning, with Poison on one side and skull and crossbones on the other, while the tablets as marketed today by The Norwich Pharmacal Company are not the same with respect to embellishments as marketed by them previously.

The Commissioner of Patents has denied our application for patent on the grounds that it is lacking in patentable novelty, in view of what is shown in design patent 20135, Booth, September 9, 1890—bottles and figures, however, if there is any possibility of amending the present application or in formulating a new joint application for a design patent to be assigned to the American Pharmaceutical Association we will gladly join with Mr. Franklin M. Apple and any others who may have any rights in the matter. We also shall be pleased to encourage and support proper legislation to make the coffin-shaped the sole type for Bichloride of Mercury antiseptic tablets and to restrict this design or shape to that purpose only. As a matter of fact, we have taken considerable interest in this phase of the question and have communicated and corresponded with members of the Legislature in several of the different States.

Thanking you for the courtesy which you have already displayed and awaiting your further valued advice, we remain,

Cordially yours,

THE DRUG PRODUCTS CO., INC.,

H. NOONAN, President.

New York, April 20, 1914."

The following communication has been received from George M. Beringer, Chairman of the Committee on Unofficial Standards, under date of April 25, 1914:

"At the Nashville meeting, the Committee on Unofficial Standards was instructed to forward to the Editor of the JOURNAL the

monographs for standards, when tentatively adopted, for publication in the JOURNAL, and to make a report on same to the Council.

In compliance with this instruction, I will report for the Committee that we have forwarded to Editor Beal monographs on the following subjects:

Agaricus	Amari Corticis
Albumen Ovi Recens	Oleum Aurantii
Asclepias	Florum
Baptisia	Oleum Bergamottæ
Delphinium	Oleum Myrciæ
Dioscorea	Ovum Gallinaceum
Fraxinus	Passiflora
Fructus Rubi	Pumex
Fructus Rubi Idaci	Sambucus
Fructus Solani Carolinensis	Senecio
Gemmæ Populi	Strontii Carbonas
Juglans	Succus Citri
Juniperus	Succus Pomorum
Lac Vaccinium	Trifolium
Menyanthes	Trillium
Oleum Aurantii	Verbena
	Vitellum Ovi Recens."

The following communication has been received:

"Mr. J. W. England, Secretary, Council A. Ph. A., Philadelphia, Pa.:

Dear Sir—At a meeting of members of the American Pharmaceutical Association residing in San Francisco and vicinity the organization of a San Francisco Branch was proposed. It was decided to petition the Council for permission to permanently organize. I am enclosing a petition asking that permission.

The proposed Branch will meet on the second Tuesday of the month. The next meeting has been called for May 12th, 723 Pacific Building, San Francisco. I do not know the exact procedure to become officially recognized, but I hope we may organize permanently on that evening.

Very truly yours,

(Signed) CLARISSA M. ROEHR,
Secretary *pro tempore*.

San Francisco, April 17, 1914."

To the Council of the American Pharmaceutical Association

We, the undersigned, members of the American Pharmaceutical Association, respectfully petition your honorable body to permit the establishment of a local Branch to be known as the San Francisco Branch of the American Pharmaceutical Association:

Val. Schmidt, 1845 Polk St.

S. A. Sharp, 1845 Polk St.

H. L. McDonnell, S. E. Cor. Powell and Geary Sts.

Claude T. Headen, 201 Frederick St.

John H. Dawson, 2489 Howard St.

Stewart McGee, 1635 Julia St.

J. G. Munson, 54 N. 5th St., San Jose.

Edward F. Varney, 1301 Broadway, Oakland.

R. A. Leet, 1301 Broadway, Oakland.

Frank T. Green, 500 Devisadero St.

H. B. Carey, 1294 7th Ave.
 Arthur Reum, 1291 Stanyon St.
 Albert Schneider, 723 Pacific Bldg.
 T. L. Lengfeld, 1350 Sutter St.
 J. M. White, 416 Hayes St.
 A. A. Poehner, 1515 Golden Gate Ave.
 Tony Prior, 282 San Jose Ave.
 James H. Winter, 1375 Valencia St.
 Carl F. Stange, 1400 18th St.
 Westersvon Krakan, 2801 Bryant St.
 J. H. Flint, 2489 Howard St.
 David H. Fletcher, 3993 Washington St.
 Philomena M. N. Goodman, 3163 Mission St.
 J. W. Boyken, 2574 Mission St.
 Henry M. Donahue, 2290 Market St.
 John Zieg, 35 Second St.
 Clarissa M. Roehr, University Hospital.

Motion No. 32 (Organization of San Francisco Branch, A. Ph. A.). Do you approve of the organization of the San Francisco Branch of the American Pharmaceutical Association?

J. W. ENGLAND,
 Secretary of the Council.

415 N. Thirty-third Street.

COUNCIL LETTER No. 19.

PHILADELPHIA, PA., April 30, 1914.

To the Members of the Council:

The following letter has been received from President George M. Beringer:

"CAMDEN, N. J., April 28, 1914.

To the Council of the American Pharmaceutical Association:

Gentlemen—There has arisen a situation in respect to the Section on Commercial Interests that I believe is without precedent and is not covered by the by-laws.

At the Nashville meeting, Mr. Gus Lindvall was elected Chairman of this Section. On March 26th, Mr. Lindvall wrote to the President that he had sold out his drug business in 1913 and had planned a trip abroad and would not be present at the Detroit meeting. He was of the opinion that his Associates, because of other duties or uncertainty of attending the meeting, were not in a position to assume the chairmanship of the Section and prepare the necessary programs. On April 9th, Mr. Lindvall wrote to your President tendering his resignation.

Immediately on receipt thereof, your President engaged in correspondence with the Secretary of this Section and the Associates elected at the Nashville meeting. There was no time to lose if a satisfactory program was to be arranged for the sessions of the Section at the Detroit meeting as provided for in the program. As the result of our correspondence and at the request of the Associates, Mr. Harry B. Mason has consented to accept the chairmanship of this Section. I am pleased to make this appointment subject, of course, to the approval of the Council.

In the absence of a precedent, I am not sure of the authority of the President to fill such vacancies, but assume that my action in this matter will meet with the approval of the Council.

Mr. Mason's recognized ability and energy and his past work in behalf of the Association bespeak a good program and successful meetings of this Section at Detroit. Mr. Mason's appointment as Chairman of this Section, doubtless, will carry with it his appointment as an ex-officio member of the Council the same as that of other Chairmen of Sections. Yours sincerely,

GEORGE M. BERINGER, President."

Motion No. 33 (Approval of Appointment of Harry B. Mason as Chairman of Committee on Commercial Interests). Do you approve appointment of Harry B. Mason as Chairman of Committee on Commercial Interests?

J. W. ENGLAND,
 Secretary of the Council.

415 N. Thirty-third Street.

COUNCIL LETTER No. 21.

Philadelphia, Pa., May 22, 1914.

To the Members of the Council:

The following communications have been received from Julius A. Koch:

PITTSBURGH, May 15, 1914.

Prof. Julius A. Koch, Pittsburg College of Pharmacy, Pittsburg, Pa.:

DEAR SIR—We have duly received your letter of May 9th and in accordance therewith and in keeping with our previous letter, we enclose herewith a formal assignment of a patent on Antiseptic Leaves to the American Pharmaceutical Association.

This assignment is made absolute as in the case of the coffin-shaped tablet. We understand that it will only be effective so far as the Association is concerned provided this form is made official.

We would also like to suggest that so far as it may be practical, the Association use its efforts to secure a price maintenance plan on the sale of this article for the benefit of the pharmacists of the country, for were we to continue in the exclusive manufacture, we would endeavor to protect the retail druggist so far as the legal limitations would permit.

We are glad to place this article in the hands of the Association and hope that our action may be of value to the pharmaceutical world at large. Very truly yours,

THE WM. S. MERRELL CHEMICAL CO.,
 CHARLES F. MERRELL.

"ASSIGNMENT."

WHEREAS, Charles G. Merrell and R. W. Proctor, both citizens of the United States, residing at Cincinnati, in the County of Hamilton and State of Ohio, have invented a new,

original, and useful improvement in packages for Antiseptic Poisons, for which they made application for letters patent, which was filed in the United States Patent Office upon February 7, 1914, and serially numbered 817,364; and

WHEREAS, The Wm. S. Merrell Chemical Company, Inc., duly incorporated under the laws of the State of Ohio, and doing business at Cincinnati, in the County of Hamilton and State of Ohio, has acquired the entire interest in said invention and in and to the letters patent of the United States to be obtained therefor; and

WHEREAS, The American Pharmaceutical Association, Inc., duly incorporated under the laws of the State of* _____, and doing business at _____, in the County of _____, and State of _____, is desirous of acquiring an interest in said invention and in and to the letters patent of the United States to be obtained therefor. Now, therefore,

Be it known that for and in consideration of the sum of one dollar, to us in hand paid, the receipt of which is hereby acknowledged, and other valuable consideration, the said The Wm. S. Merrell Chemical Company, have sold, assigned and set over, and do by these presents hereby sell, assign and set over unto the said American Pharmaceutical Association, Inc., its successors and assigns, the entire right, title and interest in and to the said design and in and to the letters patent of the United States which may be granted therefor; and we do hereby authorize and request the Commissioner of Patents to issue the said letters patent to the said American Pharmaceutical Association, Inc., in accordance with this assignment.

In testimony whereof, we have hereunto set our hand and affixed our seal this _____ day of _____, 1914.

(Signed) GEORGE MERRELL,
President.

Witnesses: Charles H. Busch.

J. W. ENGLAND,
Secretary of the Council.

Saturday.

- 9:00 a. m. Meeting of the Council.
- 10:30 a. m. Final General Session.

Do you approve the above program? This will be regarded as *Motion No. 35 (Approval of Program for 1914 Annual Meeting.)*

J. W. ENGLAND,
Secretary of the Council.

UNITED STATES PUBLIC HEALTH SERVICE.

List of Changes of Stations and Duties of Commissioned and Other Officers of the United States Public Health Service for the Seven Days Ended April 22, 1914.

Rucker, W. C., Assistant Surgeon-General. Directed to proceed to Sandy Springs, Md., April 21, 1914, and to Rockville, Md., May 5, 1914, for the purpose of delivering lectures on "Rural Sanitation." April 17, 1914.

Carter, H. R., Senior Surgeon. Detailed to represent the Service at a meeting of the Section for the Eradication of Malaria of the Drainage Congress, to be held at Savannah, Ga., April 22, 1914. April 20, 1914.

Brooks, S. D., Senior Surgeon. Granted 6 days' leave of absence from April 18, 1914. April 17, 1914.

Williams, L. L., Surgeon. Directed to instruct an officer under his charge to proceed to East Hampton, N. Y., not later than April 19, 1914, for special temporary duty. April 18, 1914.

Cobb, J. O., Surgeon. Detailed to attend the meeting of the American Nurses' Association, to be held in St. Louis, Mo., April 23, 1914, and present a paper on "The Potential Influence of the Nurse in the Health of the Nation." April 14, 1914.

Guiteras, G. M., Surgeon. Directed to proceed to Havana, Cuba, for period not to exceed one week, to study plague situation and measures in force for its eradication. April 18, 1914.

Perry, J. C., Surgeon. Granted 46 days' leave of absence, with pay, from April 14, 1914, and 12 months' leave of absence, without pay, from May 30, 1914, with permission to go beyond the seas. April 15, 1914.

Nydegger, J. A., Surgeon. Directed to proceed to the Immigration Station, Ellis Island,

N. Y., when most convenient, and remain for a few days, for the purpose of witnessing the various tests there used for the determination of mental development. April 18, 1914.

Gardner, C. H., Surgeon. Granted two days' leave of absence from April 17, 1914, under paragraph 193, Service Regulations. April 17, 1914.

Lavinder, C. H., Surgeon. Relieved from duty in charge of the Marine Hospital at Savannah, Ga., and directed to proceed to Ellis Island, N. Y., and report to the Chief Medical Officer for duty. April 6, 1914.

von Ezdorf, R. H., Surgeon. Directed to extend the work of investigations and studies of malaria so as to include the states of Kentucky, North Carolina, Oklahoma, Tennessee, and Texas. April 15, 1914.

Corput, G. M., Surgeon. Detailed at the request of the President of the State Board of Health of Louisiana, to attend the meetings of the Louisiana State Health Officers, the Louisiana State Medical Association, and the Conference for the Betterment of Health Among Negroes, to be held in New Orleans, La., April 20-25, 1914. April 18, 1914.

Ramus, Carl, Surgeon. Granted 12 days' leave of absence, on account of sickness, from April 10, 1914. April 18, 1914.

Schereschewsky, J. W., Surgeon. Directed, after having completed the necessary steps preliminary to the investigation into the sanitary condition of the garment workers' trade and the physical status of the employes engaged therein in New York, N. Y., to return to Washington, D. C., for preliminary work in regard to methods for the determination of the presence of noxious gases in the air, and in connection with hygienic conditions of illumination. April 15, 1914.

Glover, M. W., Surgeon. Granted 16 days' leave of absence, on account of sickness, from March 23, 1914. April 18, 1914.

Pierce, C. C., Surgeon. Directed to proceed to Gaithersburg, Md., April 17, 1914, and to Brookville, Md., May 12, 1914, for the purpose of delivering lectures on "Rural Sanitation." April 17, 1914.

de Valin, Hugh, Passed Assistant Surgeon. Directed to proceed to Laytonville, Md., May 8, 1914, and to Silver Springs, Md., May 15, 1914, for the purpose of delivering lectures on "Rural Sanitation." April 17, 1914.

Preble, Paul, Passed Assistant Surgeon. Directed, upon receipt of instructions from the officer in charge of the investigation of the pollution of the Ohio River, to proceed to Cincinnati, Ohio, to familiarize himself with the organization, scope, and plans of the investigation. April 14, 1914.

Thometz, H. M., Assistant Surgeon. Granted one day's leave of absence *en route* to Seattle, Wash. April 15, 1914.

Galloway, T. C., Assistant Surgeon. Directed to report to commanding officer of the revenue cutter "Unalga" at San Francisco,

Cal., for duty on summer cruise in Alaskan waters. April 1, 1914.

Porter, J. Y., Quarantine Inspector. Directed to proceed to Havana, for conference with Cuban authorities relative to plague infection at that port. April 20, 1914.

Willetts, David C., Technical Assistant. Directed to proceed via Washington, D. C., to Milledgeville, Ga., for duty in field investigations of the public health. April 20, 1914.

La Grange, J. V., Pharmacist. Granted one day's leave of absence, April 16, 1914. April 15, 1914.

CASUALTY.

Acting Assistant Surgeon B. F. Duke died at Pascagoula, Miss., April 7, 1914.

BOARDS CONVENED.

Boards of medical officers convened to meet Monday, April 27, 1914, at 10 o'clock a. m., for the physical examination and the presentation of questions for the mental examination of candidates for appointment as Assistant Surgeons in the Public Health service, as follows:

Marine Hospital, Stapleton, N. Y.

Detail for the board:

Senior Surgeon G. W. Stoner, chairman.

Assistant Surgeon-General W. C. Rucker, Chairman.

Assistant Surgeon-General J. W. Trask, Member.

Passed Assistant Surgeon Hugh de Valin, Recorder. May 11, 1914.

Board of medical officers convened to meet

at Detroit, Mich., for the re-examination of a detained alien.

Detail for the Board:

Senior Surgeon H. W. Austin, Chairman.
Assistant Surgeon J. H. Linson, Member.
Acting Assistant Surgeon K. L. Weber,
Recorder. May 11, 1914.

Official:

RUPERT BLUE,
Surgeon-General.

Changes of Address

All changes of address of members should be sent to the General Secretary promptly.

The Association will not be responsible for non-delivery of the Annual Volume or Year Book, or of the JOURNAL unless notice of change of address is received before shipment or mailing.

Both the old and the new address should be given, thus:

HENRY MILTON,
From 2342 Albion Place, St. Louis, Mo.
To 278 Dartmouth St., Boston, Mass.

Titles or degrees to be used in publications or in the official records should be given, and names should be *plainly* written, or type-written.

BROWN, C. L.,
From Letterman Gen. Hosp., San Francisco, Cal.
To Attending Surgeon's Office, Soldiers' Home, Washington, D. C.

BERNARD, P. A.,
From 258 W. 74th St., New York, N. Y.
To G. P. O. Box 45, or 662 West End Ave., N. Y., N. Y.

BEHRE, JOHN R., Serg. 1st Cl.,
From Division Hospital, Manila, P. I.
To Department Hospital, Manila, P. I.

COUSSANS, BETTIE PRINCE,
From 5125 Morgan St., St. Louis, Mo.
To Sherman Hospital, Sherman, Texas.

DIETZ, H. W.,
From Augur Barracks, Jolo, P. I.
To Field Hosp. No. 4, Ft. Wm. McKinley, Rizal, P. I.

DAHL, FRED,
From 148 Parker St., Newark, N. J.
To 52 Shepard Ave., East Orange, N. J.

FEIN, MARY AUGUSTINE,
From 1114 Thayer Ave., Little Rock, Ark.
To Little Rock, Ark.

GEDDES, MRS. L. M.,
From 393 Cambridge St., Allston, Boston, Mass.
To 1377a Commonwealth Ave., Allston, Boston, Mass.

GENOCHIO, EDW. P.,
From care Medical College, Ft. Worth, Tex.
To 1709 Jackson Blvd., Apt. K, Chicago, Ill.

HOEY, CHAS. E.,
From 11 Frederick St., S. Framingham, Mass.
To 459 Dudley St., Roxbury, Mass.

HOLT, FRANK,
From Post Hosp., Torrey Barracks, P. I.
To Camp John Hay, P. I.

LEE, J. V.,
From 829 Davis St., Evanston, Ill.
To N. E. cor. Main St. and Chicago Ave. Evanston, Ill.

MALLARD, A. E.,
From 32 Adams Ave., N., Detroit, Mich.
To 287 Woodward Ave., Detroit, Mich.

OSBORNE, WM., JR.,
From Danforth, Mo.
To Presque Isle, Me., P. O. Box 304.

PARKER, G. R.,
From 227 Plainfield St., Providence, R. I.
To 22 Pocasset Ave., Providence, R. I.

PAUL, GEO.,
From Ft. Mills, Corregidor, P. I.
To 226 Superior St., Salem, Ore.

PIERSON, ROMAINE,
From 108 Fulton St., New York, N. Y.
To 81-83 Fulton St., New York, N. Y.

WALL, O. A.,
From 4332 Virginia Ave., St. Louis, Mo.
To 4106 W. Pine St., St. Louis, Mo.

WHITNEY, DAVID,
From 4342 Campbell St., Kansas City, Mo.
To 714 Wyandotte St., Kansas City, Mo.

THE OLD AND THE NEW.

Because something recently introduced may prove highly useful, we must not jump to the conclusion that it should supersede everything long similarly used with great success. Though the trend of modern progress is ever forward, we are often forced to realize that some of our best recent achievements do not equal some of the triumphs of an earlier period. Notably is that true in the field of art, though illustrations are not lacking elsewhere. The ablest sculptors of our day have not equaled the sublime creations of their illustrious colleagues among the ancient Greeks and the Italians of the sixteenth century. No painter of our time has given us anything quite comparable with the masterpieces of Raphael and Correggio, of Titian and Rembrandt, Jacob Ruysdael, Holbein, Velasquez, and many others. Though the modern piano has utterly eclipsed the old-time spinet and harpsichord, and though, in technique and tone, the world has not seen the equal of such men as Liszt and Rubenstein, Paderewski and Mark Hamburg, no living composer has written anything which classes with the great works of Beethoven, of Mozart, Schumann and Chopin, while in the field of the musical drama the world is still waiting for the worthy successor of Wagner; and while the piano and its great exponents have scored such signal triumphs, no contemporary violin maker has equaled a Stradivarius or an Amati, and no wizard of the bow, now before the public, will claim to be the rival of Paganini. The modern express train and the giant ocean liner are immeasurably ahead of the stage coach of our ancestors and the galley of the ancients. The high powered automobile has utterly outstripped the horse, and can easily distance the stoutest thoroughbred, yet there are no indications that the noble animal will be permitted to become extinct or to revert to the type of his diminutive prehistoric ancestor; and though by reason of certain very narrow and ill-advised legislation, notably in our Empire State, the thoroughbred has suffered a sad diminution in value, in England and some other countries where broader and more enlightened ideas and cleaner politics have prevailed he is held in universal admiration, and the sport of kings still flourishes as of yore.

The foregoing random illustrations should remind us that, while we do well to remain alert and watchful for substantial improvements, we should hold on with a firm and unrelaxing grasp to everything which long experience has proved to be good.—*R. Ottolengui, M. D. S., LL. D., D. D. S., in Lehn & Fink's Dentist's Diary.*

THE ADVANTAGE OF DISCOUNTING BILLS.

It is the part of good business policy to make every effort to discount bills. Money can be used in no better way. From 2 to 10 percent is offered on ten-day discounts on drug, merchandise, cigar, gas and other bills. This is well worth picking up. It is almost like finding money. Almost anything else may be properly neglected to conserve the money for discounting bills. Aside from the money saved, it gives you a standing with the wholesalers and jobbers that nothing else will. Such standing is a valuable asset in the business world, and one that every business man should strive to gain. It means larger opportunities and will be a strong help in times of financial trouble.—*W. S. Adkins in The National Druggist.*

INDEPENDENCE NUMBER

Let our object be, our country, our whole country, and nothing but our country.

—Webster.

HARMONY.

IN every co-operative undertaking, whether it be great or whether it be small, the most essential thing to its success is Harmony; the co-operation of all its forces in harmonious relation one with the other. And *per contra* the influence which is most disastrous and which most effectually results in non-success, in any undertaking, from that of the marriage-relation to that of the greatest co-operative undertakings, is dissonance, or lack of Harmony.

Those who are placed at the forefront of any undertaking, especially those to whom are entrusted the vital interests of any great body of men, cannot too deeply allow this thought to sink well into their minds, and to highly resolve that, so far as in them lies, they will endeavor to agree with their fellows and to subordinate all other desires, all other interests, to the central idea of Service to those who have honored them with their trust and confidence. *Noblesse oblige* should be their constant thought; that the high rank to which they have been elevated entails upon them the obligation to subordinate selfish and narrow interest to the good of those who have trusted them; who have deemed them wise and able to lead them out of the wilderness, into the smooth and peaceful plains of prosperity and peace.

It is somewhat regrettable that in the Symposium on the Harrison Bill, which appeared in the June issue of the JOURNAL, a note of dissonance should be apparent, and that a lack of concord among the members of the Drug Trades Conference should seemingly be noted.

The American Pharmaceutical Association, in formulating the plan for this conference, was actuated by the one high and noble purpose;—that of Service to the Drug Trade of the country, by opposing a bulwark of defense against the absurd and freakish legislation proposed, most of which, through ignorance of

conditions on the part of those proposing it, threatened to harass and annoy the honest and well-meaning members of the profession, while accomplishing but little of good result to the people.

There was no selfish thought in that effort. It was simply a wise attempt to unite all interests for mutual protection, and its wisdom has been proven by the results already achieved. Is it not possible for the members of this conference to place the greater interests of our profession above that of everything else, and to make that the bed-rock, the sole motive of all their acts? Or is it impossible for some men to forget their own selfish interests for a time and to act in a large and liberal way; in a way comprehensive of the general good?

Some one has written, "In essentials, Unity; in non-essentials, Harmony; in all things, Charity." Let this be the rule for the conduct of the business of the Conference, and the results achieved by it will be enhanced a thousand-fold. If we might be allowed to drop into slang, as Silas Wegg dropped into poetry, we might advise the members of the Conference to "Get together," and, forgetful of self, think only that the well-being and the destiny of a noble profession is in their keeping, and that its dignity and its welfare is in their care. "'Tis nae feesh yere buyin, it be men's lives," as the old fish-wife told the chaffering Laird, and it is not the interest of self or of the moment, that should guide the action of the members of the Drug Trade Conference, but the weighty thought that upon their wise action depends the welfare, the happiness, the destiny of the thousands of druggists, and of their wives and children, of this broad land.

The responsibility rests upon the members of that Conference to see that these interests are conserved and fostered, and it is greatly to be hoped that they will rise above all slighter considerations, and use their magnificent opportunity in a manner that will not only redound to their credit and honor, but also for the general welfare of the whole profession, which needs brave, strong, unselfish leadership, to guide its members in these troubled days.

A FEW NOTES OF INTEREST ABOUT THE CONVENTION CITY.

Detroit was an outpost of the *Coueurs de Bois*, those famous wood-rangers, hunters and trappers of Canada; those outlaws against whom Louis the Grand, of France, launched those edicts intended to prevent their leaving the homes in which he was determined they should abide; to follow their own bent as free rangers of the forest; as men free from those laws which made them serfs and slaves of the nobles under the reign of the *Grand Monarque*, who thought all his subjects were born to minister to his pleasure. Pontchartrain was one of those nobles to whom *les droit des seigneurs* was a God-given right. I have wondered if the name Detroit had relation to these edicts of Louis, which were intended,—as were those he fulminated against the Protestant Huguenots,—to force them to do his will or to destroy them;—the French verb "*Détruit*" being the past participle of "*Détruire*," which means, "*to destroy*." I cannot find any other derivation for its name stated anywhere, but perhaps I am far from the fact.

The Jesuit Father, Cadillac, is considered to be the founder of the city. In

June, 1701, he went there with about 100 men and built a fort, but before his time in 1686, Fort St. Joseph had been built, which showed that trade had already found it an attractive place before his arrival. Fort Gratiot now stands on the site of the old Fort St. Joseph.

Around this fort of Cadillac thronged the savage tribes of Ottawas and Foxes, the Wyandots and Crees, the Sacs and Senecas, the Delawares and Shawanees. Pontiac, the famous chief of the Ottawas, lived on a small island at the entrance

The P. D. Co.'s Stmr. Pleasure.

of Lake St. Clair. Every step a visitor takes here, is reminiscent of the trying experiences of our fore-fathers with the Indians; the latter, to be sure, often wronged. Here the readers of Parkman's "Conspiracy of Pontiac" will tread on familiar ground. Here civilization met barbarism; drove the aborigines from their homes and hunting-grounds to make this a beautiful city; one of the jewels of the Republic. To one interested in the early days of our land,—and what loyal citizen is not,—a visit to this district should prove most interesting and

instructive. England's flag floated over Fort Pontchartrain during our War for Independence and again, during the war of 1812, when it was captured by the British, but the peace of 1813 brought it once more to be American territory.

To-day, the most charming summer-city of America is making ready to receive the members of the A. Ph. A. to their hearts and homes. Charming Belle Isle, Grosse Pointe and the attractive Bois Blanc, (Bob-Lo) Flats are putting on their best array, and there is no member of the association, or a druggist in all America, but will receive a bountiful return for his attendance upon the Convention. "Get out and get under!" "Get out" of your narrow environment, your limited circle, and "get under" the movement to lift Pharmacy out of the sordid slough of commercialism, into its true heritage, that of noble and an honored profession.

ENTERTAINMENTS.

Monday:—Grand Ball, Hotel Pontchartrain. Evening.

Tuesday:—Nelson Baker's Excursion for ladies. Afternoon. Boat-ride and dinner at "Bob-Lo" Park.

Wednesday:—F. F. Ingram & Co. and the F. A. Thompson Co.'s Theatre-Party for ladies. Evening.

F. Stearn's Co. Social "Smoker" for gentlemen. Evening.

Thursday:—Parke, Davis & Co.'s Steamer-excursion up the river and through Lake St. Clair. For Everybody.

Friday Afternoon:—Automobile-trip, through the beautiful suburbs of Detroit. The Lake-side Drive. Belle Isle.

Saturday:—Farewells.

THE attempt of the Board of Pharmacy in Massachusetts to determine its powers over the establishment of chain-stores, in that Commonwealth is greatly to be commended.

Because the Court has decided that the contention of the Board,—that the Riker-Jaynes Company was not a corporation entitled to conduct the drug business because the majority of its stock-holders were not registered pharmacists,—was wrong, does not make that contention a less true or a less just one. If a syndicate of men who were not lawyers should form a corporation and attempt by the employment of lawyers to do business in that Commonwealth under their own corporate title, it is safe to say that the Honorable Justices would bar them from any appearance before the Court under their corporate title, even though their employes had been admitted to the bar, and it is difficult to see wherein the case differs from this one, where the members of this corporation are not registered pharmacists of the State of Massachusetts, and yet seek to make appearance before the public as such.

"And ne'er shall the sons of Columbia be slaves,

While the earth bears a plant or the sea rolls its waves."

—Robert Treat Paine.

PORT COCKBURN TRIP.

The rates for this most delightful excursion have been made at a figure which should tempt all the members attending the convention to take advantage of this opportunity to see this most delightful pleasure resort of the country.

The itinerary with rates is as follows: From Detroit to Toronto, to Bala, (the gateway to the Muskoka Lakes), a delightful water trip through the entire Muskoka Lakes to Port Cockburn, a short interesting stage ride to Maple Lake, a still shorter rail trip to Rose Point, a yacht trip to Parry Sound, thence a delightful water trip through the celebrated 30,000 Islands of the Georgian Bay to Penetang, rail to Toronto to Detroit, one of the most popular trips through the Highlands of Ontario. The total cost of the trip is \$17.50 (exclusive of meals and berth), and the following shows approximate schedule. The trip may be broken at Toronto, Bala, Royal Muskoka Hotel, Port Cockburn, Parry Sound, etc., or any point desired. Limit of tickets Oct. 31st, 1914.

Daily						
Mon.	Lv.	Detroit	CPR	*12:50 AM	*Sleeper open at 9:00 PM	
Tues.	Ar.	Toronto	CPR	8:25 AM		
Tues.	Lv.	Toronto	CPR	9:45 AM	11:50 AM	
Tues.	Ar.	Bala	CPR	1:54 PM	3:40 PM	
Tues.	Lv.	Bala	MNCo.	3:50 PM	3:50 PM (Wed)	7:20 AM
Tues.	Ar.	Beaumaris	MNCo.	4:45 PM	4:45 PM
Tues.	Ar.	Port Carling	MNCo.	5:35 PM	5:35 PM	9:10 AM

Thurs.	Lv.	Penetang	GTR	12:20 PM		
Thurs.	Ar.	Toronto	GTR	3:45 PM		
Thurs.	Lv.	Toronto	CPR	4:00 PM	7:35 PM	{ Remain in sleep- er until 8:00 AM
Fri.	Ar.	Detroit	CPR	11:30 PM	1:40 PM	

Lower berth fare between Detroit and Toronto \$1.50, Upper berth fare \$1.20, Drawing Room \$6.00. Parlor-car seat fare, Toronto to Bala \$0.50.

An interesting side trip from Parry Sound to Point Au Baril, Georgian Bay, which is fast becoming the most popular resorts in the Highlands of Ontario can be had for \$2.85 which covers rail transportation Parry Sound to Point Au Baril Station, thence boat to either the Ojibway, Bellevue or Skerryvore Hotels, which Hotels are situated on beautiful islands in (Point Au Baril), Georgian Bay District. Return same way.

Gauserie

IF WE KNEW.

If I knew you, and you knew me;
 If both of us could clearly see,
 And with an inner sight divine
 The meaning of your heart and mine,—
 I'm sure that we would differ less,
 And clasp our hands in friendliness;
 Our thoughts would pleasantly agree,
 If I knew you, and you knew me.

—Anon.

The Columbus Branch will soon be "Topping" all others.

Dr. James H. Beal, the Editor of the Journal, is soon to leave Scio for his camp in Canada, where he will find much-needed relief and rest by getting close to nature and breathing the ozone of the pine-clad hills of the primeval forests. Dr. Beal was present at the meeting of the North Carolina Association at its meeting at Hendersonville, on June 17-18-19, and delivered an address on the first day of the Convention.

It is reported that a hungry man once said, "That his stomach had been asking his mouth if his throat was cut for some time." Apropos of this *ana* the humble A. E. would inform the Honorable Treasurer that his correct address is

63 CLINTON BUILDING, COLUMBUS, OHIO,

and that, "*Bis dat qui cito dat.*"

Mrs. John G. Godding, the President of the Women's Section, was the guest of Anna G. Bagley, the Secretary of the Section, for a few days last month, on her return from the Federation of Women's Clubs at Chicago. Prof. and Mrs. Kaufman gave a dinner-party to Mrs. Godding, on the evening of her departure from Columbus, at their charming home in Maple Grove.

The Acting Editor is practicing writing with both hands, in order to use the fountain pens sent to him from the Boston Association of Retail Druggists, with a handsome leather manuscript-carrier, all from the same kindly friends.

Between the farewell kindness of Boston and the welcoming kindness of Columbus, the A. E. is wondering if he had not better heed the maxim of the Japanese, "When things are coming your way, look out!", but in the meantime he is sincerely grateful for the many kindnesses showered upon him, is happy in his work and is earnestly desirous of "grappling to his soul with hoops of steel" all his friends, by loyal, faithful service to the important interests, temporarily placed in his care.

The Editor has been requested to call the attention of the members to Article 2, Section X, of the By-Laws, which refers to the reading of papers before the Sec-

tions, and prints the Article for the information of those desiring to present papers:

Article II. Any person desiring to submit a paper to the Association shall present to the Chairman of the particular Section to which it refers, at least ten days prior to the meeting, an abstract of said paper, indicative of its contents, and consisting of not less than fifty nor more than two hundred words.

This abstract shall be printed as a part of the program. The paper itself must be submitted to the officers of the Section previous to the first session. Not more than ten minutes shall be allowed for the presentation of any paper, unless by unanimous consent of the Section. This does not apply to the Scientific Section, which handles its papers in accord with the By-Laws of said Scientific Section.

All papers presented to the Association and its branches shall become the property of the Association, with the understanding that they are not to be published in any other publications than those of the Association, except by the consent of the Committee on Publication.

RATES AND ROUTES FOR ATTENDING THE A. PH. A. CONVENTION TO BE HELD IN DETROIT, AUGUST 24TH TO 29TH, INCLUSIVE.

PRELIMINARY ANNOUNCEMENT.

Office of Chairman Committee on Transportation, 166 Chambers St., New York.

New York and New England: All rail to Detroit. Arrangements have been made with the Walter H. Woods Co., 262 Washington St., Boston, Mass., for an 18-day tour by New York Central Lines to Detroit, and return by way of Toronto, Lake Ontario, Thousand Islands, St. Lawrence River, Quebec and Montreal, thence through Central Vermont or the D. & H. Co. lines to Boston and New York.

The price of above tour, including railroad fares, Pullman, meals, rooms at Hotel Pontchartrain while in Detroit, with bath (2 in room); railroad and steamer fares with meals on St. Lawrence River trip, five days' room and board at Murray Isle Hotel at Thousand Islands, rooms and meals at other hotels and cars enroute, except meals while in Detroit,—

New York and return, 18 days, \$123. Basing on 10 or more people.

Boston and return, 18 days, \$124. Basing on 15 or more people.

Rate from Detroit, 11 days from date of departure to arrival in New York or Boston, \$85. Descriptive circulars of this tour will be sent on application.

Train will leave South Station, Boston, August 22d, at 4.45 p. m., connecting in Albany, N. Y., at 9.40 p. m., with party from New York leaving the Grand Central Station at 6 p. m. This train will arrive in Detroit on Sunday, August 23d, at 1.30 p. m.

Rail and Lake Route, New York: Philadelphia, Baltimore and Washington to *Detroit*, by Lehigh Valley Railroad and connections to Niagara Falls and Buffalo, thence by steamer of the Delaware and Cleveland Navigation Co. to Detroit.

August 22d—Leave Washington by 3 p. m. train, B. & O. R. R. Leave Baltimore, 3.58 p. m. train, B. & O. R. R. Leave Philadelphia, 6.30 p. m. train, P. & R. R. R., which will meet the 6 p. m. train on Lehigh Valley from New York at South Bethlehem at 8.50 p. m., arriving Niagara Falls 7.10 a. m., Sunday, August 23d; leave Niagara Falls on day coach 4.22 p. m. same day, arrive Buffalo, 5.25 p. m. Leave Buffalo on D. & C. Co. steamer at 6 p. m., arriving in Detroit Monday, August 24th, 7.30 a. m.

Single fares, Washington to Detroit.....	\$14.63—parties of ten	\$12.45
Single fares, Baltimore to Detroit.....	\$13.63—parties of ten	\$11.70
Single fares, Philadelphia to Detroit.....	\$13.10—parties of ten	\$11.75
Single fares, New York to Detroit.....	\$12.00—parties of ten	\$10.95

A charge of 50 cents for transfer of baggage from train to boat in Buffalo.

From Cincinnati: Chicago, Hamilton & Dayton route is recommended; single fare to

Detroit \$5.25; no reduction for parties. Railroad can be taken to Toledo and thence by White Star Steamer to Detroit at same fare; Pullman and staterooms extra.

From Cleveland: Where Tourist rates to Detroit are to be had it is best to purchase them. From points not having Tourist rates, purchase fare to Cleveland.

Cleveland to Detroit, via D. & C. Boat Line—leaves 11.45 p. m., Eastern time.

Fare—one way, \$2.00.

Fare—round trip, \$3.50.

Fare—round trip, parties of ten, \$3.00.

State rooms, \$2.50—accommodate three persons.

Those wishing to take a day ride on the lake, leave Cleveland at 8.30 a. m., Eastern time, arrive at Put-in-Bay at 12.45, leave Put-in-Bay, 3.30, arrive in Detroit, 8.00 p. m.

This historic island is well worth seeing, also the beautiful new monument, in honor of Commodore Perry's victory, which is about completed.

Transfer of boat is made at Put-in-Bay. This is no hardship as boat for Detroit is at same dock.

Fare—one way, \$1.50. Round trip, \$2.50.

On return trip from Detroit stop at Cedar Point, "Coney Island of the West," great place for conventions, well worth your while to visit. Take boat for Cleveland about 4.30 p. m. same day.

If further information is required, write

LEWIS C. HOPP, 1104 Euclid Ave., Cleveland, Ohio.

From Atlanta: Members from Southeast are advised to route via Louisville and Nashville, Atlanta to Cincinnati, C. H. & D. to Toledo, Pere Marquette, Toledo to Detroit, or by White Star Steamer, Toledo to Detroit, as they may prefer. L. & N. train schedules are as follows:

Leave Atlanta 7.12 a. m., arrive in Detroit 7.45 a. m. following day.

Leave Atlanta 5.10 p. m., arrive in Detroit 4.45 p. m. following day.

One way rate Atlanta to Detroit, \$18.50; parties of ten, \$15.20, or round trip summer tourist tickets can be purchased for \$30, limited to October 31st return.

From New Orleans: Illinois Central to Chicago, Michigan Central to Detroit. Tickets on sale daily, good to return until October 31st. Fare, single, \$43.00 in parties of ten or more, \$22.00;—sleeper extra. For direct information, address Edward Roddy, 144 St. Charles St., New Orleans.

From St. Louis: The St. Louis party for the Detroit meeting of the A. Ph. A., August 24th, will make use of the Wabash. The summer rate for the round trip from St. Louis to Detroit is \$16.00. Tickets are good for thirty days from date of sale. Tickets will be honored going direct and returning via Chicago or going via Chicago and returning direct, or going and returning via Chicago. For an additional \$5.00 tickets will be honored for the boat trip via Mackinac Island and Chicago. The fare for Pullman sleeper, lower berth, is \$2.50 each way, direct between St. Louis and Detroit.

Special excursions are sometimes given between St. Louis and Detroit, and it is possible that in this way a much lower rate will be available for the Detroit meeting. Further information can be obtained by applying to H. M. Whelpley, 2342 Albion Place, St. Louis, Mo.

Pacific Coast Points: Round trip tickets to Chicago will be sold only on August 17th, 18th, 20th and 21st for \$72.50, good for return until October 31st, with stop over privileges. Tickets sold for one line good for return over any other line, but if members from San Francisco elect to travel by way of Portland over the Shasta route, an extra charge of \$17.50 each way will be made.

From Chicago to Detroit the regular rate prevails, which is \$5.50 each way, or \$11 round trip, or members may on the dates above mentioned purchase excursion tickets from Pacific points to New York and return for \$108.50, securing stop over at Detroit for Convention and other stop overs if desired.

Further details regarding rates and routes may be obtained from the nearest member of the Committee on Transportation, whose addresses follow:

COMMITTEE ON TRANSPORTATION.

Thos. F. Main, Chairman.....	New York, N. Y.	L. A. Seltzer.....	Detroit, Mich.
W. Bodemann.....	Chicago, Ill.	E. Floyd Allen.....	Minneapolis, Minn.

Fred I. Lackenbach.....	San Francisco, Cal.		

Respectfully submitted,

THOMAS F. MAIN, Chairman.

St. Paul and Minneapolis:—

One way, \$13.55.

Round trip, \$27.00.

The Great Western and the Milwaukee railroads will furnish a special car for parties of twelve or more.

For further information, write

E. FLOYD ALLEN,
1538 Nicollet St., Minneapolis.

Nashville, Tenn., and other Southern points:—

Memphis, \$29.15, via either Chicago or Cincinnati.

Chattanooga, \$24.55, via Cincinnati only.

Knoxville, \$22.25, via Cincinnati only.

Nashville, \$22.75, via either Chicago or Cincinnati.

Louisville, \$15.25, via Cincinnati only.

Frankfort, \$15.25, via Cincinnati only.

Lexington, \$14.70, via Cincinnati only.

These tickets are on sale daily up to and including September 30th, good returning October 31st and permit of liberal stop-over privileges.

For further information, apply to

DR. J. O. BURGE, or GEORGE E. HENRY,
District Passenger Agent, Nashville, Tenn.

The world will little note or long remember what we say here, but it never can forget what they did here. The brave men, living or dead, who struggled here have consecrated it far above our power to add or to detract.

It is for us, the living, rather, to be dedicated here to the unfinished work which they who fought here have thus far so nobly advanced. It is rather for us to be here dedicated to the great task remaining before us; that from these honored dead we take increased devotion to that cause for which they gave the last full measure of devotion; that we here highly resolve that these dead shall not have died in vain; that this Nation, under God, shall have a new birth of freedom; and that government of the people, by the people and for the people, shall not perish from the earth.—*Lincoln at Gettysburg.*

Book Reviews

DIGEST OF COMMENTS ON THE PHARMACOPOEIA OF THE UNITED STATES—(Eighth Decennial Revision), and on the National Formulary, (Third Edition), for the Calendar Year Ending December 31, 1912. By Murray Galt Motter and Martin I. Wilbert, Washington Government Printing Office, 1914.

This volume is one, which, however valuable in other ways, is not, at all, true to its name, "A Digest of Comments on the U. S. P. and N. F.", because it contains so much matter foreign to its title that it seems but a cloak,—for a book, which really is a schedule of miscellaneous articles which have appeared in the press, without regard as to whether the subject referred to, was included in either of the volumes mentioned in its title. For instance, on page 76,—to open the book at random,—are found the following references:—

"Progress in Gas Analysis during 1911.

"Review of Progress in Stoichiometry.

"A Report on the Progress of Pharmaceutical Chemistry, etc.

"A Review of the Progress in Pharmaceutical Chemistry.

"Progress in Pharmaceutical Chemistry during 1911.

"A Note on Sampling.

"The Various Analytical Researches on Ions.

"The Influence of the Solvents on the Rapidity of Reaction.

"Pharmacists and Physicians Have Been Entirely Too Lax in Demanding the Purest and Best Drugs in Combating Disease.

"Many manufacturers and physicians have not much use for 'adulterated,' they prefer the word 'technical,' which means the same and is not so harsh.

"There is more adulteration, and certainly more misbranding, among drugs to-day than there is to be found among food products.

"A brief discussion of the general topic of drug adulteration, for which the cure suggested is education and standardization."

It is difficult to understand how any of these references can be included in a book bearing the title "A Digest of Comments on the U. S. P. and N. F.", for none of them refer in any way to either volume, or to its preparations, and the same is true throughout the whole manual, page after page containing nothing referring to either book.

"The Digest of Comments" on the U. S. P. and N. F.", as originally planned, was one which should include comments, favorable or unfavorable, concerning the contents, make-up, processes, formulas, manipulations, etc., of these two important books, and a treatise, if worked out along those lines, would prove of immense advantage to the profession, but such comments, if they are contained in the volume in question, are so overlaid and covered up by extraneous matter that their value is entirely destroyed.

It is much to be desired that "A Digest of Comments," true to its name, should be prepared and kept up-to-date, as a help to all interested in the two volumes, and, at the same time, we trust we may be pardoned for suggesting that further issues of the pamphlet under discussion should be published under a title more descriptive of its contents.

Scientific Section

Papers Presented at the Sixty-First Annual Convention

A NEW UTERUS-CONTRACTING METHOD OF TESTING ERGOT,— WITH COMPARISON WITH THE BLOOD-PRESSURE METHOD.

• PAUL S. PITTENGER, PHAR. D., AND CHAS. E. VANDERKLEED, PHAR. D.

It is well known that non-striated muscular tissue exhibits automatic (spontaneous) rhythmic contractions. It is also well known that certain drugs have the power of stimulating and thereby increasing these normal muscular movements. Various methods of standardizing ergot have been devised and employed by competent pharmacologists utilizing these facts. In most cases, however, the muscle was suspended in oxygenated Ringer's solution, contained in a Harvard muscle warmer with a capacity of about 40 cc. and in practically all cases the Harvard light muscle lever was employed for recording the contractions.

The non-concordant results obtained by other workers with isolated uteri have been ascribed to the interference of spontaneous contractions and the increasing irritability of the muscle tissue under the continued influence of the drug. These two factors form the principal objections to uterine methods. Pharmacologists have therefore endeavored to overcome these objections by selecting the uteri of animals manifesting the *least degree of normal movements*,—preferably those of the cat. To illustrate, Edmunds and Hale, in reporting their observations upon the non-pregnant uteri of cats, state in Bullétin 76, Hygienic Lab. U. S. Pub. Health and Marine Hospital Service: "It is true that the uteri of young cats which may be perfectly quiet in the earlier stages of an experiment after some time may begin to contract spontaneously and increase the difficulty of making comparisons of the effects from successive injections of the drug." In such cases, the authors state, "it may be necessary to employ as a standard the smallest amount which will clearly influence these movements, as, for example, by delay in the relaxation."

The uteri best adapted to our method, on the contrary, are those which manifest a *high* degree of normal spontaneous movements, preferably those of a non-pregnant guinea-pig, weighing between 275 and 325 gms. Instead of employing a Harvard light muscle lever we attach the free end of the uterus by means of a silk thread to one side of an escapement wheel, to the other side of which is suspended a counterpoise bucket for holding shot. By adding the proper amount of shot to this bucket the operator is enabled to weight the uterus down and thus reduce the amplitude of these movements so they can be controlled. Thus the marked spontaneous contractions can be reduced until the uterus is just able to contract under the increased load, or in other words, shot is added until the maximum amount of work that the uterus is normally capable of performing

FIGURE 1.—Arrangement of the apparatus employed.

FIGURE 2 is a graphic drawing of the apparatus and will serve to illustrate the following detailed outline of the method which we employ.

is counterbalanced. Any increase in the amplitude of the contraction after the addition of a given drug can now be produced only by that drug.

As is to be expected, the addition of weights necessitates the employment of larger doses of the drug in order to produce marked contractions but, on the other hand, the resultant contractions are more nearly parallel to the doses given. (See Figure 4).

The uterus is suspended in about 250 cc. of Ringer's solution contained in a cylindrical glass vessel (G), the lower end of which is plugged with a rubber stopper (O) having a central bore. Through the latter passes one arm of a wide glass "T" tube (J) which ends flush with the upper surface of the stopper, so that the cylindrical vessel may be completely emptied. This tube passes through a second rubber stopper (L) which fills an opening in the bottom of an outer metallic vessel (F) which forms a constant temperature water jacket.

The temperature of the water in the jacket is kept constant by means of a metallic rod (E) which penetrates the wall of the jacket, passes through the water, and is soldered to the opposite side of the jacket. The portion of the rod external to the jacket is heated by a protected Bunsen burner (C) which slides on the rod. The temperature is regulated by sliding this burner backward and forward until that point is reached where the amount of heat transmitted by the rod to the water inside is sufficient to keep the thermometer (T) suspended in the water at the proper degree (38° to 39° C.)

One of the other arms of the "T" tube is connected by a rubber junction (X) armed with spring clamps (S) to a waste pipe by which the cylindrical glass vessel may be emptied.

The remaining arm is connected by a syphon tube (D) to a flask (B) which holds a small amount of Ringer's solution for refilling the cylindrical vessel. This flask is kept at a temperature between 40° and 45° C. by means of a steam bath (Z). The main supply of Ringer's solution is contained in a large aspirator bottle (A) connected with the small flask by a rubber tube (W), the object being to avoid exposing the reserved solution to prolonged heat. Heat causes Ringer's solution to gradually decompose and lose CO_2 .

The Ringer's solution in the small flask should be reduced to 39° C. immediately before admitting it to the cylindrical vessel by allowing sufficient cold solution to run into it from the aspirator bottle.

Into the cylindrical vessel containing the Ringer's solution dips a narrow glass tube (Y). This tube is turned at right angles about half an inch from its lower end. Into this is sealed a platinum pin (N) for attaching the *lower end of the isolated uterus*. The upper end of this tube is connected by means of rubber tubing (P) to an oxygen reservoir (R). A constant stream of oxygen is allowed to bubble through a small vent at the lower end of the tube, thus preserving the muscular irritability of the uterus and at the same time stirring the Ringer's solution.

The other end of the uterus is fastened to a small platinum hook (I) connected to a silk thread (V) which passes over an escapement wheel (H) and is attached to a pin on the opposite side of the wheel. A counterpoise bucket for holding shot (U) is attached to the opposite side of the wheel. To this wheel is soldered an stylet of aluminum (K); the axle of the wheel serving as

a fulcrum. To the end of this stylet a pen point is fixed (Q) for recording the contractions of the uterus on the revolving drum of the kymograph.

Method of Procedure.—The animal is bled by quickly severing the carotid artery with a sharp-pointed scissors. The spinal column is then severed with a strong scissors. One horn of the uterus is then quickly excised together with the ovary which is left attached by means of the fold of broad ligament in which the Fallopian tube runs. This horn is then quickly transferred to the oxygenated Ringer's solution in the cylindrical vessel and attached to the two platinum pins above referred to (the ovary is fastened to the hook suspended from the escapement wheel and the lower end of the horn is fastened to the pin at the lower end of the oxygen tube). The manipulation and exposure followed by the immersion in the warm solution will almost invariably produce a high degree of tonus, which, however, gradually diminishes until the uterus returns to its normal condition. If at this point the uterus does not exhibit *strong* rhythmic contractions it should be discarded and replaced by a new one. The weights are now added by dropping shot into the bucket *until the uterus can make only small rhythmic contractions*.

Conditions are now suitable for determining the activity of the drug to be tested or standardized. The samples to be tested are first freed from alcohol by evaporation on a water bath and then made up to their original volume with water.

A small dose (0.3-0.5 cc.) of the standard preparation is now pipetted into the Ringer's solution in which the uterus is suspended. If all conditions are ideal the uterus which was recording small rhythmic contractions will now forcibly contract and record its contractions by a long sweeping curve. After the curve reaches its maximum and commences to decline (which may require from 5 to 15 minutes) the medicated Ringer's solution is quickly run off and replaced by fresh solution, previously adjusted to the proper temperature. The momentary exposure to the air while changing the solution generally causes the uterus to contract rather forcibly, thus markedly increasing the amplitude of the curve produced by the action of the drug. It is necessary, therefore, in changing solutions to hold the escapement wheel for a few seconds or until the uterus is again covered with the saline solution. This will prevent the record from being interrupted by contractions not produced by the drug. The curve now quickly returns to normal and the uterus continues to record its small rhythmic contractions.

Should the uterus chance to be a *very sensitive* one, a dose of 0.5 cc. of the standard preparation may produce a contraction so strong that it will carry the writing pen off the smoked chart. In such cases it is necessary to reduce the dose. If, however, the uterus still continues to give such marked contractions, shot should be added until the contraction can be controlled. On the other hand, should a dose of 0.5 cc. not produce contraction, the dose should be increased to 1 or 1½ cc. If, however, doses of 1.5 cc. do not call out contractions, shot should be removed until a marked contraction is produced by these doses.

After thus adjusting the apparatus two successive doses of equal amounts of the standard solution should be given. If the resultant contractions are equal the uterus is giving concordant results and is ready for assay purposes. In

FIGURE 3.—Demonstrates first, the normally acting uterus (A to B); second, the action when weighted down by shot, (B to C); and third, the action of ergot on the uterus when loaded and working against resistance (1, 2 and 3).

FIGURE 4.—Demonstrates first, the normally acting uterus (A to B); second the *non-concordant* results produced by repeated doses of the same amount of fluid extract ergot (1, 2, 3, 4, 5, 6 and 7); third, the *concordant* results obtained after the uterine contractions are controlled by weights (8, 9 and 10). The curves G and H indicate the quantitative results obtained by a larger and a smaller dose.

order to determine the relative activity of an unknown preparation it is now merely necessary to give progressively increasing or decreasing doses of the unknown preparation until that amount is found which will produce contractions of an equal amplitude as those produced by the standard preparation.

Description of Charts.—The terms “no weights” and “weights added” used in this paper refer to the shot used in inhibiting the normal contraction of the uterus, not to the counterpoise employed to keep the uterus suspended in the Ringer’s solution.

FIGURE 5.—This illustration is similar to Figure No. 2. A to B show normal contractions; 1, 2, 3, 4, and 5, show non-concordant results obtained without weights; 6, 7, 10, 11, 12, and 13, show concordant results obtained after weights were added. The curves 8 and 9 indicate contractions produced under increased stimulation due to a rise in the temperature of the Ringer’s solution, and show the necessity for maintaining an even temperature during the experiment.

During our experiment we were greatly impressed by the differences in the uteri as to power and muscular structure, and their mutual relation. Some specimens were greatly deficient in muscular substance and acted feebly. Other specimens showed greater muscular development and contracted strongly. Some of the specimens proved absolutely inert and would not respond at all. After more extended experience, however, we found that the normal activity practically runs parallel to the amount of muscular tissue present; the “stringy” uteri are all deficient in normal activity and in response to stimuli, while the thick, more muscular uteri are practically all active and sensitive. This knowledge enables us to save considerable amounts of time as it renders it pos-

sible for us to distinguish between active and inactive uteri before connecting them with the apparatus.

Having at one time a series of unsatisfactory results which extended over a period of one week, we were at a loss as to the cause of this sudden change in the efficiency of the test. After careful investigation, however, we found that our stock of Ringer's solution was unsterile and showed bacterial growths. New solution was made and placed in sterile containers, after which our results were again concordant. This emphasizes the necessity for keeping both the solution and syphon tubes in a sterile condition.

Due to the marked difference in the sensitiveness of the various uteri, it is

FIGURE 6.—This chart clearly demonstrates the concordant results from repeated doses of an equal amount of fluidextract ergot, 3, 4, 5, 6, 7, 8, 9, and 10; 1, 2, and 11, indicate the quantitative results obtained by varying the doses and demonstrate the accuracy of the test.

necessary to employ a standard preparation with which to compare the unknown preparations. These comparisons must, of course, always be made on the same uterus.

As a standard we employ a fluidextract or ergot of such strength that when injected intravenously into a series of three or more dogs, it produces an average rise in blood pressure of 30 mm. of mercury. After preparing a standard preparation of the above strength it is placed into 4 cc. vacuum ampoules to prevent deterioration. These can then be opened and used as required.

The marked sensitiveness of this method, together with the concordant results obtained by the same, led us to believe that by its use we could perhaps ascertain whether or not the uterine and circulatory actions of ergot run

parallel to one another. This is an important factor, since the blood pressure method is rather extensively used for standardization purposes, its employment being supported by statements that the characteristic effect of ergot is a stimulation of all unstriated muscle tissue of the body, and that the changes in the circulation, in the intestines and in the uterus are but a part of one general action. The employment of this method has been further supported by the fact that all of the substances which have been suggested by various writers as the active principles of ergot have produced stimulation of the blood-vessels as well as of the uterus. So far as we are able to learn, however, no experimental results have ever been published to show whether or not these two actions run parallel.

We are, therefore, now testing every sample of ergot submitted for assay by both the uterine and blood pressure method. By this means we will be able after a sufficient number of samples have been tested to compare the results obtained and thus determine whether or not a parallelism does exist between these two actions. If on completion of our experiments the results show that all the samples which assayed high by the blood pressure method also assayed high by the uterine method we will know that these actions do run parallel. If, on the other hand, some samples run high by one method and low by the other, we will know that such a parallelism does not exist.

Up to the present time we have made comparisons with seven samples with the following results:

Preparation.	Comparative strength by B. P. method.	Comparative strength by uterine method.
No. 1 F. E.....	166%	170%
No. 2 Cornutol	100%	90%
No. 3 F. E.....	153%	148%
No. 4 F. E. 5 mo. old.....	51%	100%
No. 5 F. E.....	224%	230%
No. 6 F. E.....	210%	198%
No. 7 F. E.....	118%	105%

The above table would indicate that a parallelism does exist between the action of ergot upon the circulatory system and the action upon the uterus. We will, however, be unable to arrive at a definite conclusion until more data has been compiled.

We will, therefore, continue our investigations along these lines for another year.

RESEARCH LABORATORY OF H. K. MULFORD COMPANY, July 28, 1913.

THE PROPOSED LIST OF USEFUL REMEDIES.*

M. I. WILBERT, WASHINGTON, D. C.

For more than a decade men who are genuinely interested in the development of pharmacy as a recognized and necessary branch of medicine, have viewed with alarm the ever-growing accumulation of disparaging evidence, on the part of national and state food, dairy and drug officials, and have urged upon the fellow-

*Read before the Scientific Section at the Nashville Meeting.

members of their craft a more active propaganda to secure for true pharmacy the recognition and respect that is properly due it for services rendered. These seers, dreamers and reformers have, however, up to the present time, railed in vain and some indeed have passed on to their final accounting without even the flicker of a promise that pharmacy,—the pharmacy which they loved so well and for which they sacrificed their all,—would ever again resume the comparative position of honor accorded it in the earlier days of medicine.

Unfortunately, too, it must be admitted that pharmacy in European countries,—to which we have in the past looked, with something akin to awe, for inspiration and support,—appears to be undergoing a degenerative commercialization, and in Germany, particularly, many of the followers of the craft have undertaken to vie with larger manufacturers in the production of proprietary remedies of little or no value. To such an extent has this commercialization of German pharmacy and pharmaceutical chemistry been developed, that members of the medical profession of that country have felt compelled to institute a Commission or Committee on New Remedies, with objects similar to those of the Council on Pharmacy and Chemistry of the American Medical Association. This Commission, though working along somewhat different lines from those laid down by the Council on Pharmacy and Chemistry in our own country, is destined to bring about a decided change in the methods of marketing proprietary remedies in Germany, and the objections already recorded in medical and pharmaceutical journals, evidence the fact that the work is opportune and that it is meeting with the approval of medical men.

It will generally be admitted that the fundamental object of pharmacy is to maintain the purity and efficiency of the medicines used for the treatment of disease. If this truism be accepted as law, then any person or any collection of persons not in accord with it, as the essential principle of pharmaceutic practice, must, of necessity, be considered as being out of harmony with the interests of true pharmacy, and unfriendly to the real object of our vocation. That there is considerable difference of opinion in regard to the maintenance of the accepted efficiency of materia medica products by the votaries of pharmacy, is evidenced by the fact that many pharmacists, or so-called pharmacists, aver that it is their duty to supply the medicaments asked for, without making any serious effort to differentiate between good and indifferent remedies or between efficient and inefficient methods of administering them. This purely servile attitude has prevailed altogether too long in American pharmacy and was branded as one of its essential shortcomings by the institution of the Council on Pharmacy and Chemistry of the American Medical Association some eight years ago.

Despite the fact that the American Pharmaceutical Association, as an association, has never taken an active interest in the work of the Council on Pharmacy and Chemistry, individual members of this Association have, from the very origin of the Council, taken a prominent part in its evolution and development. In the course of time, the work of the Council on Pharmacy and Chemistry has developed, and in place of involving, as formerly, principally questions of pharmacy or pharmaceutical chemistry, the problems under consideration to-day frequently involve questions of bacteriology, pharmacology and practical therapeutics, and the *personnel* of the Council has of course materially changed. De-

spite this fact, however, even at the present time fully one-half of the members of the Council on Pharmacy and Chemistry of the American Medical Association are also members of the American Pharmaceutical Association.

The origin and object of the Council have been discussed at length in the pages of the Journal of the American Pharmaceutical Association (v. 1, p. 39), and those of our members who are interested, will find a recent *resume* of its activities by Torald Sollmann, in the Journal of the American Medical Association, (July 15, 1903, v. 61, p. 5-7).

The main object of the Council on Pharmacy and Chemistry has well been defined as the general reformation of what is debased and debasing in the present status of drug therapy, and in the course of their work, the members have become convinced that a very fair proportion of the physicians of the country are desirous of securing authoritative information regarding the present status of all remedies, and are quite willing to accept reasonable opinions regarding the value or uselessness of official, as well as of non-official medicaments. To establish an authoritative compend of widely used drugs, the Council has endeavored to compile a list of really useful remedies. Such a list, it was thought, would be of great practical value as a factor in advancing drug therapy along scientific lines, as well as in combating the evils of nostrums of all kinds. It was also thought that such a list would be of use as a basis for instruction in materia medica subjects in medical schools, and as a reasonable limitation for examinations in materia medica subjects, by state medical examining boards.

With the very limited amount of time that can be devoted to materia medica, in the present-day curriculum of medical schools, it is evident that it would be practically impossible to teach all that is known of the five thousand or more drugs and preparations comprised in the several pharmacopœias of the world, to say nothing of giving even the most superficial survey to the countless hundreds of articles mentioned in dispensatories and other books of reference. Thorough instruction regarding the properties, uses and limitations of a reasonable number of widely used medicaments, it was argued, would serve to give to the prospective practitioner of medicine a reliable foundation in materia medica subjects, on which he would be able to develop a practical and safe materia medica for himself.

A list of useful remedies, to serve the purposes outlined above, should include all articles regarding which a prospective graduate from a medical school, or a reasonably well informed medical practitioner, might be expected to have a fair amount of information. With the constant, and at times rapid, changes in our knowledge regarding the possible action and uses of drugs, this list must, of necessity, be more or less ephemeral, and be modified, from time to time, so as to include only the articles that are being actively used and discussed in all sections of the country, if not in all parts of the world.

A tentative list of important medicaments was compiled in 1908, under the direction of the Council on Medical Education of the American Medical Association, by the Sub-committee on Pharmacology, Toxicology and Therapeutics. This list was later submitted to the National Federation of State Medical Examining and Licensing Boards, who endorsed the principle involved and appointed a special committee to compile a list adapted to the needs of state medical

examining boards. From this latter list, the Council on Pharmacy and Chemistry, through the Sub-committee on Useful Remedies, compiled a preliminary list of widely used articles, and this list was then sent to teachers of pharmacology and therapeutics in medical schools and colleges, to deans of medical schools and colleges, to the secretaries and some of the members of state medical examining boards, and to a number of medical practitioners who were thought to be interested in the subject. The replies received from these several sources were compiled, and the revised list was subsequently submitted for discussion and additional comment, through the pages of the Journal of the American Medical Association.

So far as practicable, in the present knowledge of the usefulness of medicines in therapy, an effort has been made to include in the list of useful remedies, only such drugs as are generally acknowledged to have superior medicinal value, or which, because of their supposed value, are still in general use in all parts of the United States. This principle does not, of course, exclude drugs regarding which pharmacologists have decided opinions as to their worthlessness, but it does limit the inclusion of such drugs to a reasonable number, and it may properly be expected that, in the near future, reliable clinical observations will definitely prove the value or uselessness of the limited number of drugs of this kind.

How successful the Council has been to compile a really international list of useful remedies, is evidenced by a comparative review of the present list with the articles included in the several well known pharmacopœias of the world. The total number of titles and headings in the present list can be classed as follows:

Drugs or chemicals.....	231
Preparations	173
Class definitions	43
Cross references	13

Of the 231 titles of drugs or chemicals, all but one, salvarsan, N. N. R., are included in one or more of the now existing pharmacopœias and, of the remaining number, again, all but one, phenolphthalein, are included in two or more of the now official pharmacopœias. The recognition accorded the several articles in 16 national pharmacopœias is approximately as follows:

95 are included in all 16 pharmacopœias.
80 are included in from 10 to 15 pharmacopœias.
27 are included in from 5 to 9 pharmacopœias.
25 are included in from 2 to 4 pharmacopœias.
1 is included in but one pharmacopœia.
1 is not official at the present time.

The object of bringing this matter to the attention of the members of the Scientific Section of the American Pharmaceutical Association, is to point out that much, if not all, of the dissatisfaction with established medicaments, may be due to the fact that, as they reach the patient, they are not strictly in accordance with the requirements of the Pharmacopœia.

This rather bold, bald statement may be questioned by some, but when it is remembered that, for a decade or more, incontrovertible evidence to this effect has been accumulating, and is readily available, it would appear that the

rational course for pharmacists to pursue would be to assist in correcting existing evils and to insist that all readily controlled drugs be sold or dispensed only in full compliance with established standards.

It will generally be admitted that, under present-day conditions, it is impracticable, adequately, to control, by chemical or other means, all of the many drugs and medicines dispensed on physicians' prescriptions. With the establishment of a reasonably limited list of drugs and preparations, however, it would be possible for the pharmacist to comply with the requirements of established standards and to satisfactorily control the identity and purity of the medicaments so listed. Such a limited list of substances would also facilitate systematic study of the deterioration or changes of drugs and preparations and the methods best suited for preventing them. How little we really know of the chemical behavior of even the best known drugs and preparations has again been emphasized by Neuberg and Shewket (*Biochem. Ztschr.*, p. 495-501), who, in a report of studies on changes in medicaments caused by light, call attention to the possible photochemical action of iron, and point out that solutions of otherwise indifferent materials may be decomposed by light, in the presence of salts of iron, into physiologically active substances. The possibilities suggested by this report alone, offer material for study for many years to come, and this study, if concentrated on a reasonably small number of drugs and preparations, would yield practical results of value to the medical practitioner of the future.

In conclusion, I will venture the assertion that the active coöperation of the various branches of pharmacy, in protecting a reliable materia medica, will tend to strengthen the faith and reliance of medical practitioners in really useful remedies, will assist in eliminating perfunctory drugging with useless mixtures, and will lead to a rational, scientific study of the action of drugs on the healthy and on diseased organisms, and thus serve to place drug therapy on a reasonable and secure foundation for all time to come.

DISCUSSION.

Wm. Mansfield, of New York, said that he thought the use of vegetable drugs in the last fifty years had been increasing gradually in this country, and all over the world. He was in touch with a great many people interested in these things, and was sure that there was a movement going on to bring back vegetable drugs. He believed that, while this list was helpful, it was really not a restricted list, but a prepared list, which included standards of purity, tests of identity, for every drug and preparation used in medicine. He thought the person in a small country place, who bought a few pounds of drugs, was as much entitled to receive pure drugs as the man manufacturing thousands of pounds. The interests of such men should be taken into consideration, as well as the results of the comparatively few men in the laboratory.

In response to a question by Mr. Murray, Mr. Wilbert said there was a larger book in process of publication now. He believed this was to be obtained, at the present time, from the offices of the *Journal of the American Medical Association*.

Continuing, Mr. Wilbert said that the paper would serve to record an effort to get at the things most used at the present time and to secure reasonable uniformity.

Papers Presented at the Sixty-First Annual Convention

THE TABLET INDUSTRY—ITS EVOLUTION AND PRESENT STATUS.

Continued from Page 848, June issue.

L. F. KEBLER, PH. C., M. D.

BASES.

These are cane sugar, milk sugar, ammonium chlorid, citric acid, sodium carbonate, and sodium chlorid. When an excipient is used to increase the weight of granulation or the size of a tablet or to facilitate the solubility of an active agent, it is termed a base. Milk sugar, for example, is commonly mixed with certain triturations in sufficient quantities to produce tablets of a given size. Sodium carbonate is a commonly used base in the manufacture of calomel triturates. Milk sugar is now universally employed for the manufacture of molded tablets, not solely for its action as a base, but because of its adhesiveness and the property it possesses of producing tablet of a porous nature, a property of great service in preparing tincture triturates. Mixtures of cane and milk sugars can often be employed to advantage. Ammonium chlorid, sodium chlorid, and citric acid not only add bulk, but facilitate the solubility of corrosive sublimate.

DISINTEGRATORS.

Starch and gelatine are used for this purpose. At one time a mixture of bicarbonate and citric or tartaric acid was employed. The most commonly used disintegrator at present, however, is starch. Its value lies in the property it possesses, when dry, of absorbing moisture and expanding, thus disintegrating the tablet. Such tablets when properly made should fall into powder almost immediately on immersion in water. The amount of starch used varies from 5 to 20 per cent, depending upon the nature of the ingredients. Even after starch was quite generally employed as a disintegrating agent, much criticism on the score of "insolubility" was still forthcoming. The first observation on "insolubility" recorded after Killgore's application for a patent will be found in Arnold's remarks.⁴⁶ This observation is referred to by Dieterich.⁴⁷ It should be noted, however, that there is a possibility that the knowledge of the properties of starch as a disintegrator had not at that time found its way into Germany. In 1899, J. E. Groff,⁴⁸ twelve years after Killgore's discovery, refers to the finding of undisintegrated quinine tablets in the excrement of patients. Joseph R. Wood,⁴⁹ in 1904, refers to the uncomplimentary term "brickbats," then applied to tablets, largely on the ground of their "insolubility." Such tablets are stated

⁴⁶ Corr.=Bl. f. Schweiz. Aerzte, 1890, 20: 94.

⁴⁷ Pharm. Ztg., 1890, 35: 400.

⁴⁸ Am. Drug., 1899, 34: 196.

⁴⁹ Am. Drug., 1904, 44: 105.

to be distinctly unsafe in typhoid fever. C. S. N. Hallberg,⁵⁰ in 1901, made an investigation of the time required to disintegrate tablets in artificial gastric and intestinal juices, with unfavorable results in a number of cases. Some believe that these unsatisfactory tablets were due to inexperience, lack of care, or too much adhesive, but after twenty years' experience some non-disintegrating tablets are still encountered, and the question is being studied. For example, Lowry⁵¹ proposed the use of starch paste, instead of starch, to cause more ready disintegration. The discussion of the paper clearly shows that all of the difficulties in regard to disintegration have not yet been solved. In 1909, H. Dichgans⁵² recorded some results where tablets had not disintegrated at the end of twenty-four hours, and Seel and Freiderich,⁵³ in 1911, reported on tablets which would not disintegrate in water.

Some are of the opinion that the kind of starch used is of the utmost importance; others think that cornstarch is as well adapted for the purpose as potato starch. Very few observations on this point have been published, the most comprehensive being those of Blaschnek,⁵⁴ in 1909. His investigation included potato, wheat, corn, rice, and marantha starches. The results clearly show a distinct advantage for marantha and potato starches. These two, according to his observations, seem to run nearly parallel. The point made by this investigator is that the starch must be nearly anhydrous if the best results are desired. The criticism on this point by some is, that if the starch is too dry the tablet has a tendency to disintegrate spontaneously, due to the moisture absorbed from the atmosphere. Blaschnek, however, claims that this criticism is not well founded, though his observation in this direction is not borne out by many other observers. Gelatine acts like starch, but the results are generally unsatisfactory, and it is, consequently, very little used at present. The mixture of a bicarbonate and an acid when immersed in water reacts and gives off carbon dioxide, thus mechanically breaking up the tablet. This method, as far as the writer knows, is not practiced now. Powdered agar-agar and Irish moss have been advocated as disintegrators, but so far they have not been used to any extent.

ABSORBENTS.

These include milk sugar, starch, magnesium carbonate, and powdered licorice root. The purpose of these agents is to absorb moisture or medicated liquids. For example, starch is frequently mixed with extracts, not only to facilitate drying, but also to act as a disintegrator when the material is in tablet form. Milk sugar constitutes the base of most of the hypodermic tablets, is an excellent absorbent, and produces porous tablets. Tablets are medicated homeopathically by simply adding the medication in liquid form and allowing the liquid to evaporate. Magnesium carbonate and powdered licorice root are not so well adapted for absorbing moisture as starch.

LUBRICANTS.

In the compression of drugs difficulty is generally experienced because the material adheres to the punches and dies. Agents used to minimize this diffi-

⁵⁰ Merck's Rept., 1901, 10: 211, 245.

culty are called lubricants. A few granular compounds, like sodium bromid, potassium iodid, chloral hydrate and hexamethylamin, do not need lubrication. Dunton included lubricants and certain methods of application in his patent of 1875.⁵⁵ The principles announced then still hold to a large extent. A few new lubricants have been added. Those in use at present are talcum, liquid petrolatum (white oil), theobroma oil, boric acid, starch and stearic acid.

Purified talcum is the most common and abundantly used lubricant. It is used both alone and in conjunction with "white oil." The amount varies from one to five percent, based on the weight of the granulation, but the writer has found as much as 30 percent in the finished product. The addition is usually made to the granulation and is never employed in soluble tablets. Talcum is generally added for the purpose of overcoming "picking."

Liquid petrolatum ("white oil") of suitable quality is very generally used, both alone and in conjunction with talcum. It tends to prevent "sticking." About one drachm to each pound is ample. It should be used either not at all in the manufacture of soluble tablets, or as sparingly as possible, because it has a tendency to retard solution and produce milkiness. Dunton advocated the use of paraffin dissolved in a volatile solvent, over twenty-five years ago. The distribution of "white oil," cacao butter, and petrolatum by means of a volatile solvent is not productive of the best results. Experience has shown that the solution penetrates the granules and thus deposits a large part of the lubricant where it is of little or no service; furthermore, it is expensive and not without danger. Talcum and oil are frequently used together to prevent "picking" and "sticking." In analysis the presence of these lubricants should be kept in mind.

Boric acid is the only permissible lubricant for soluble tablets. When rapid solution is required the acid must be applied in an impalpable form. The amount used should never exceed 5 percent except in cases where it is one of the medicaments itself.

Theobroma oil (cacao butter), either alone or in solution, was brought forward in Dunton's patent in 1875, before mentioned. White and Rodwell are frequently given credit for its introduction into the tablet business, but this honor clearly belongs to Dunton.

Starch is not usually classed as a lubricant, although its value and usefulness for this purpose are well recognized.

Stearic acid has been advocated and used, but is not employed to any extent at present in making medicinal tablets. It is used to some extent in compressed confectionery.

FILLERS.

The term "filler" is applied to substances like terra alba, fuller's earth, kaolin, and other inorganic bodies serving the purpose of a base. They are usually considered inert and therefore harmless, but their introduction into the system must be looked upon as decidedly undesirable. Their use in confectionery is forbidden by law, and if they are undesirable for this purpose, why should they be introduced into the stomachs of the sick? There is no excuse for the practice.

Thus, it is clearly shown that the number of ingredients employed in the manufacture of tablets is legion, and all are agreed that it is absolutely necessary for

⁵⁵ U. S. Pat. 168240, dated Sept. 28, 1875.

every manufacturer to possess a great deal of knowledge as to their quality and purity, which can be gained only by proper chemical and pharmaceutical supervision.

CHEMICAL CONTROL.

The industry involves a multiplicity of details which must be carefully observed if this form of medication is to be prepared with the uniform composition usually claimed. It is necessary to know the character, purity and composition of the initial ingredients to be used. If this information is lacking it is practically impossible to even approximate in advance of analysis the amount of an active agent or agents in the finished product. The quality of medicinal chemicals available on the market is, on the whole, very satisfactory, but it would be unwise to take for granted that all of these drugs are as represented. Again, a chemical may deteriorate by being kept for an undue length of time or under improper conditions. There may be loss of water of crystallization on account of faulty containers or storage. Greater variation is liable to occur in tablets in which plant extractives are employed. These extractives are often made under the same roof as the tablets, and the possibility of taking chances under these conditions is sometimes greater than when they are purchased outside. On the contrary the quality of a home-made product is well known to the maker, and if it is carefully supervised the chances for deficiencies are diminished. The potent agents in plant products may vary to a great extent. Time is also believed to be an important factor, but this has not been definitely determined in many cases.

The use of different menstrua in extracting plant drugs causes great variation in the finished product. By using different solvents the yield may be doubled, in some cases, without correspondingly increased activity. In fact, the activity is frequently decreased in proportion to the increase of the extractive. The tablets in which such variable drugs are used cannot very well be uniform. The writer realizes that it is practically impossible to place every feature under chemical and pharmaceutical control, but in reality such a course is the only safe one.

SUPPLY AND STORE ROOM.

This is one of the most important units of the business, and should be in charge of a capable, well-trained and experienced man who should check up not only the quality and uniformity, but also the correct compounding of formulæ. In the case of habit-forming agents and expensive remedies he should be designated as the one responsible for their actual introduction. These drugs, particularly the former, may be surreptitiously spirited away, at least in part. Not a single ounce of material should leave this room without an order properly signed, stating the quantity and purpose for which it is to be used. Every formula should constitute an order by itself. It will serve as a useful record and tend to minimize errors. Laxness here has been found to lead to numerous difficulties, as will be shown later. The room should contain several compartments suited for the storage of the various drugs.

TRITURATING, POWDERING, AND MIXING.

Trituration is the process of reducing a substance to a fine or impalpable powder by grinding or rubbing. The substance to be triturated may be simple or mixed. If the several ingredients are triturated separately it will ultimately

be necessary to mix them, and it is believed that a powdering together of the active agents with a part at least of the excipient to be used often produces the best results. The mortar and pestle is the simplest trituratory, and the wedge-wood variety is the most generally satisfactory. This trituratory was formerly used almost exclusively. Fairly satisfactory results can be obtained, provided sufficient time and energy are spent. It is, however, applicable only to small batches. Apparatus has been devised for mechanically operating the mortar and pestle. Perfect triturations by this method are, however, few. The small ball mill produces better and more satisfactory results in every way.

Ball and pebble mills. These mills consist of revolving hollow cylinders of iron, steel, porcelain, and, in some cases, the metallic mills are porcelain lined. The trituration is accomplished by balls, usually of the same material, but sometimes hard, flint pebbles are employed. At times the pebbles are eroded, so that the powdered material is correspondingly contaminated. The material, with the balls, is introduced into the cylinder, the cylinder closed and rotated until the drug is of the required degree of fineness. This form of apparatus is very satisfactory for triturating hygroscopic, irritating and poisonous drugs. Porcelain or porcelain-lined mills are most satisfactory, although somewhat more expensive. Iron mills can be used only for powdering material possessing a large amount of color. Porcelain-lined ball mills vary in capacity from a few ounces to fifty pounds. A pot mill is simply a modified form of the ball mill.

Chasers may be considered as modified forms of mortars and pestles. They consist of heavy rollers rotating on a flat surface, or in a trough. These rollers are either of stone or iron. The action is slow but positive and satisfactory. They are suitable for powdering or mixing almost anything. Even white goods can be powdered in them if care is exercised. There is always some elevation encircling the rollers, to retain the material within a certain area. The entire machinery is usually enclosed in a separate chamber to avoid contamination either from the outside or by the spread of powder through a room in the course of powdering. If it is desired to prepare a special, high-grade powder, the rollers are encircled with cylinders of various heights. The higher these cylinders the finer the powder. The principle is that the rollers, in revolving, not only powder the material but also mechanically raise the finer powder in the form of dust, which falls over the side of the cylinder where it collects and can be removed. This form of apparatus is excellently suited for the preparation of high-grade, uniformly fine, soft powders. The method is, however, one of the most expensive, and is employed only for special products.

High-speed mills. For powdering large quantities, high-speed mills are essential. Very satisfactory mills are at present available. The details of construction differ, but the principle of powdering is the same. It lies in the fact that the drug is brought into contact with the beaters at a high rate of speed, varying from 2,500 to 3,000 revolutions a minute. The powder is usually kept in contact with these beaters until it is sufficiently fine to be ejected. From this it can readily be seen that the powdering is done by impact. The material is struck with repeated powerful blows and thus shattered into powder. The fineness is controlled by the rate of speed and by mechanical devices. Various in-

gredients may be simultaneously powdered, and thus mixed, but, as a rule, the several ingredients are powdered separately.

Mass mixers. This form of apparatus is suitable for the mixing of material containing more or less moisture. For example, it is of service in mixing solid extracts with powder, and it may be possible, by this form of apparatus, to mix together a product containing considerable moisture with dry material, so that it may be granulated.

Powder mixers. Various forms are available. The essential features of all are a semi-cylindrical trough, covered with a box-shaped lid, and a metallic spiral for mixing. Sometimes a sieve is placed at the bottom of one end, to guard against the introduction of material too large to pass through the sieve introduced. When two powders of materials of different specific gravity are to be mixed, great care must be taken because of the tendency of the heavier and the lighter powder to separate into layers, thus resulting in mixtures of variable composition. If the milk sugar or other vehicle is included in the mixing operation, the mixture is ready for making molded tablets, but if intended for compression the powder requires granulation.

GRANULATION AND MIXING.

Granulation is essential to the manufacture of satisfactory compressed tablets. It consists in thoroughly mixing the powders with suitable liquids and forcing the slightly dampened mass through a sieve of proper size. The granules thus formed are dried, after which the lubricant, or additional lubricant, is added if necessary, and the granules are again sifted. Certain chemicals come in granular form, or they may be readily granulated by milling and sifting. Before granulation it is important that the powder be reduced to the greatest possible degree of fineness, and that there be perfect mixture. Blaschnek⁵⁶ claims that granulation is not necessary. With this view, however, very few agree. No method has yet been devised nor any machine constructed by means of which it is possible to satisfactorily compress fine powders without undue pressure, except in the form of molded tablets. By means of granulation a friable mass is produced, whereas, if powder be compressed, the resulting tablet is hard and difficult to disintegrate, except in the case of soluble chemicals. Even an excess of fine powder mixed with the granulation often interferes with the satisfactory compression of the tablet, and is frequently responsible for undue variation in both weight and composition.

AGENTS OF A VOLATILE OR UNSTABLE NATURE.

One of the most difficult tasks of the tablet-maker is to incorporate in tablet form medicinal agents of a volatile or unstable nature. Among these are ammonium carbonate, camphor, nitroglycerin, salol, the valerianates and essential oils. One method in vogue is to mix all of the ingredients, granulate, and dry the granulation at room temperature as rapidly as possible, thus avoiding loss. In some instances, the manufacturer mixes a larger amount of the volatile drug with the granulation than is actually called for, thus allowing for some dissipation, yet preparing a finished product containing the requisite quantity of the drug. Another method consists in dissolving the volatile drugs in alcohol or

⁵⁶Pharm. Post, 1909, 42: 170.

some other volatile solvent and mixing the resulting solution with the granulation just previous to compression. This, of course, also requires a certain length of time for the elimination of the solvent. In addition there is great difficulty in uniform distribution by this procedure. For example, it would be very difficult to uniformly distribute throughout the granulation camphor dissolved in alcohol. The probabilities are that a larger proportion of the camphor would be mixed with one part of the granulation than with another part. Even should the distribution in the granulation be fairly uniform, a large amount of volatilization might still occur before the material was compressed. Neither of these procedures gives satisfactory results until the finished article is chemically adjusted.

FIG. 19—Design of dryer made by Ralph R. Patch.

business is unprofitable, he manufactures such tablets on request because he desires to hold the patronage of medical men. It is argued that if one manufacturer will not fill prescriptions calling for these commodities, another manufacturer will do so, with the resulting loss of business in other lines. The medical profession should recognize these inherent difficulties and discontinue requests for such goods. If medical men persist in their requests the manufacturer himself will be compelled in self-defense to place upon the packages of such goods labels apprising the purchaser of the situation. They are unable to guarantee the goods to be strictly in accord with the prescription on account of the volatile nature of certain of the ingredients, even though the correct quantities were used at the outset.

Another point to be considered in this connection is the fact that even after the tablets are compressed in suitable form and contain the proper amount of such active agents, there is a probability of loss by volatilization, dissociation or sublimation, resulting in a product differing in composition from the declaration appearing upon the label. In cases of this kind it is best to discontinue the manufacture of such tablets. Dealers are unable to guarantee these products for any length of time, even when the tablets are right at the outset. The claim is frequently made that this line of business is not only unsatisfactory but unprofitable, and the hope is often expressed that medical men might be induced to cease ordering goods of this character in tablet form. One manufacturer claims that even though the

DRYERS.

One of the cardinal principles in the successful manufacture of tablets is a thorough drying of the material. Dunton emphasized this feature many years ago. The dampened granules must be dried. Some drugs, both simple and

FIG. 20—Vacuum dryer.

mixed, may be sufficiently dried, under favorable conditions, in the open air, but the weather cannot be depended upon and a reliable drier must be used. It should be of the best possible construction and arranged to provide a continuous current of fresh air, at a uniform temperature, which should be under absolute control. This feature has apparently received very little attention in

the past, and is undoubtedly the cause of many shortcomings, particularly in the case of goods of a volatile or deteriorative nature. Such drugs should be dried at the lowest possible temperature. Dryers are usually heated by means of steam pipes coming from the boiler. Check valves are seldom introduced to control the heat. Observations made on some of the dryers show that the temperature varies from that of the room to 100°C. , 108°C. , 110°C. , 115°C. and even to 120°C. The air of some of these rooms is absolutely stagnant. Ventilation and change of air are dependent almost entirely upon the opening and closing of doors, a bad practice for which there is no excuse. The dryer should be so constructed as to introduce the air at the bottom, pass it over the successive trays, and finally emit it at the top. In case the granules are dried on cloth trays, such an arrangement is unnecessary. During the past decade, drying in a vacuum has been greatly improved. In a number of factories, discarded vacuum dryers have been observed, and the management stated that they were not successful. On the other hand, other manufacturers are using vacuum dryers with great success, and hold that their use is of eminent service in the proper drying of granules for compression. The writer has seen in very successful operation one of these vacuum dryers which had displaced a battery of the old form of dryers.

By means of this apparatus it is possible to conduct the drying at any ordinary temperature.

After a granulation is satisfactorily dried it is again sifted, and the lubricant, or additional lubricant, added. Flavoring agents, such as methyl salicylate, oil of peppermint, and oil of cinnamon, are also usually added at this stage, and the material is then ready for compression.

COMPRESSION OF TABLETS.

One of the prominent claims made for tablets is "uniform dosage and medication." No part of the entire process in the manufacture of tablets requires more care to produce accuracy than compression, and no feature has received greater attention. The machines now on the market are the outgrowth of many experiments to overcome the serious defects of the earlier machine. Devices of an uncertain character have given way to mechanisms of positive action. The simplest form of apparatus is the hand punch and die, useful in prescription work and in cases where only a limited number of tablets are required, but it is of little use at present. A number

FIG. 21—Hand tablet compressor.
(V. L. Kebler)

FIG. 22—Hand tablet press. (Ph. Ztg., 1902.)

of hand presses are now serving the same purpose, but their usefulness also is very restricted. The automatic power machines are universally

employed where any number of tablets are required. Of the two types of power machines, the rotary and the vertical punch, both single and multiple, many are advocated. Some do not have a good word for the rotary; others cannot praise it too enthusiastically. The modern rotary will undoubtedly turn out the greatest number of tablets in a given time, although the output of the multiple vertical, of eighteen to twenty punches, is very large. An eighty punch vertical machine has

FIG. 23—Single punch vertical tablet machine (Stokes and Company).

FIG. 24—Richards multiple punch vertical tablet machine.

recently been constructed. The first desideratum is a uniform tablet, and it is believed by many that the single punch machine has something in its favor in this direction, because there is less adjustment and alignment of punches and dies. The next essential is to prepare a tablet of such weight that the number actually produced from a given amount of granulation agrees very closely with the theoretical calculation. For example, if a formula calls for 500,000 tablets, the operator must determine the size necessary to produce approximately the theoretical number, including waste and loss. An experienced worker is able to do this very quickly.

FIG. 25—No. 2 rotary tablet machine (Colton Company).

FIG. 26—Clark rotary tablet machine (Stokes Machine Company).

VARIATION IN WEIGHT OF MEDICINAL TABLETS.

A natural query at this point is, "How closely do the theoretical and practical yields agree?" On this operators are usually too enthusiastic. When the question, "How near, in practice, do you come to the calculated?" is put to them, the almost invariable reply is, "Two percent." Some admit that the variation may run as high as 3 percent, but not one has ever admitted that the variation might run as high as 5 percent, either above or below the number calculated. The writer has been shown formula after formula where the theoretical and actual yields are identical. Only a little thought will convince any one that such a feat is a rare exception. Data of this character must be taken with a grain of salt. It is very common not to take account

FIG. 27—Bottom punch (Fraser).

of waste and dust. To provide for these it is usually necessary to start with a larger amount of material than is required by calculation. After studying the entire question carefully and interviewing many manufacturers it is believed that a variation of 5 percent above and 5 percent below the theoretical is ample and can be readily complied with. Definite data on this point are scanty and difficult to secure. Working cards do not give them. The following are a few observations specially made by request, which represent regular runs:

Theoretical yield. No. tablets.	Actual yield. No. tablets.	Waste. Percent.	Gain or loss. Percent.
210,000	217,000	1.8	+5.10
420,000	432,000	1.3	+4.10
14,000	14,250	3.5	+5.3
29,166	28,594	1.0	-2.06

Some defects contributing to variable tablets are: (1) *Improper feeding*, due to the fact that the granulation is too fine, too coarse, too damp, or contains an excess of powder, and *excessive speed of machinery*, allowing insufficient time to uniformly fill the die or dies. (2) *Worn machinery, punches or dies*. Worn machinery may produce thick tablets one moment and thin ones the next. Worn punches and dies are the cause of "picking" (adhering to the punch), "sticking" (sticking to the die) and "whiskered" tablets, that is, tablets with elevated peripheral edges which are broken off in sifting, tending to leave ragged sides. (3) *Loosening of adjustments*. (4) *Careless weighing of the finished tablets*. The usual practice is to weigh ten tablets at intervals while a lot is being run. A common prescription balance is generally employed for the purpose. A wire gauge is also used to control the thickness of the tablets, and thus indirectly control their weight. At first it was believed that this practice was an inaccurate one, but an examination of tablets from factories where the method is in vogue showed them to be as uniform as where weighing only is practiced. It should be said, however, that where a wire gauge is used, weighing also is resorted to, but not as frequently as when weighing alone is relied upon to determine uniformity.

So far as it has been possible to determine, all tablet manufacturers and chemists believe that a total variation in weight per tablet of 10 percent, 5 percent above and 5 percent below an average, is very liberal for the larger tablets, and that if a greater variation were permitted it would encourage carelessness. That there will be some variation is conceded by all, and the variation will be greater for the smaller tablets. Manufacturers have not studied the question, at least not one of those interviewed was in a position to give any information on the point. A careful search of the literature shows that comparatively little work along this line has been done by analysts. Only one article containing data on variation in weight of individual tablets by analysts in the United States was found. Four contributions embodying information on the subject by chemists of foreign countries appear in print. The earliest was by E. J. Parry and P. A. Estcourt.⁵⁷ These investigators worked on tablets of single constituents. Their results, converted into the metric system and percentage, will be found in Table I.

⁵⁷Pharm. J., 1894, 24: 592-3.

The five different kinds of tablets examined show that 50 percent exceed a 10 percent total variation, 40.9 percent a 12 percent variation, and 22.72 percent a 15 percent variation. It will undoubtedly be claimed, and with justice, that these observations were made nearly a score of years ago, and every one will admit that there have been some material improvements during that time. In order that comparison may be readily made, the observations recorded by O. Liebreich, W. A. Puckner and A. H. Clark, G. Frerichs, and Eugen Seel and Albert Friederich are unified, summarized, put on a percentage basis and given in Table 2.

¹Liebreich, O., Ther. Monatshefte, 1898, 12: 476.²Puckner, W. A., and Clark, A. H., J. Am. Med. Asso., 1908, 51: 330.³Frerichs, G., Apoth. Ztg., 1908, 23: 521, 522.⁴Seel, Eugen and Friederich, Albert, Med. Klin., 1911, 7: 888, 927, 928.

In 1898 when tabloids (a trade name for tablets) were introduced into the German army, O. Liebreich had the examinations recorded in Table 2 made. The results are fairly satisfactory. The examination of Puckner and Clark was mainly directed to the determination of the amount of phenol present in the tablets examined. The question of variation in weight was simply incidental. The results show that 54.54 percent exceed a 10 percent variation. The same degree of variation exists on a 12 percent basis, and 45.45 percent exceed a 15 percent variation; apparently not much of an improvement in fourteen years. Someone may say, "This phenol mixture is not suitable for making tablets, and if medical men write prescriptions for such compounds to be put up in compressed form, they ought to be prepared to get almost any kind of a variable article." Volatile substances like phenol should not be compressed into tablets. In arriving at a general conclusion as to the variability in the weight of tablets, volatile-bearing articles should not be included. They are in a class by themselves.

G. Frerichs inferred from the label "0.5 gram" on packages of "pyrenol" tablets that they contained nothing but 0.5 gram of pyrenol. In fact, there is little doubt, he believes, that every physician and apothecary labors under the same impression, particularly in view of the fact that the manufacturer made this claim. With these conditions obtaining he determined to make an examination of the tablets on the market, and incidentally weighed individually about thirty-two tablets. The results show a wide variation.

The observations made by Seel and Friederich on the variability of tablets were made in connection with a study of the causes of inferiority of some medications in tablet form. Their data show that tablets of acetylsalicylic acid and of pyrenol vary excessively, while tablets of two other chemicals are fairly satisfactory.

It is clearly evident that sufficient observations along this line have not been made to justify any general conclusions. The range studied must be greater in every direction. Medication in tablet form varies from a single ingredient to half a dozen or more. They contain both stable and unstable drugs, and volatile agents are also improperly put up in tablet form at times. In order to obtain extended data as to variability of weight, a large number of assorted tablets taken, first from the machines in operation, second, from trade packages as found in the market, and, third, from samples submitted by manufacturers, were weighed. The goods examined represent not only many manufacturers, both large and small, but also a liberal assortment. Twenty-five tablets were weighed in each case. The results obtained are given in Table 3.

The following summary shows the number of kinds of tablets examined, the kind of apparatus on which they were made, and the percentage of tablets having a total (above and below average) variation of more than 10, 12, 15 and 20 percent, respectively:

No. of kinds.	Variety.	Kind of apparatus.	Maximum variation of more than			
			10 percent.	12 percent.	15 percent.	20 percent.
			Percent.	Percent.	Percent.	Percent.
54	Compressed	Single punch.....	44	37	19	5.6
53	do	Multiple punch...	51	43	28	9.4
38	do	Rotary	45	28	15	5.3
11	T. T. ¹ & H. T. ²	Single punch.....	27	18	9	0.0
9	do	Multiple punch...	78	67	67	11.1
9	do	Rotary	100	89	67	55.6
57	Molded	Mold	79	56	37	10.5

The number of tablets exceeding a 10 percent variation is very high. Simple tablets do not seem to fare any better than compound ones. One type of machine yields about as good results as another for the regular compressed tablets. On the whole, the single punch appears to have a little the advantage. The rotary fares badly for the compressed tablet triturates and for the hypodermic tablets. The variation in the smaller tablets is greater than in the larger, as would naturally be expected.

Of the total number of tablets, 57 percent exceed a maximum total variation of 10 percent, 44 percent a maximum of 12 percent, 28 percent a maximum of 15 percent, and 9.1 percent a maximum of 20 percent. There is little excuse for tablets exceeding a total 20 percent limit. A 10 percent variation was generally believed to be ample, but the figures do not accord with this limitation. A 12 percent variation would not relieve the situation materially, while a 15 percent variation still leaves 28 percent exceeding this limit. The large manufacturers' goods vary in weight as much as those of the small ones. It is believed that a 15 percent variation, $7\frac{1}{2}$ percent above and $7\frac{1}{2}$ percent below the average weight,

¹T. T.=Tablet triturates.²H. T.=Hypodermic tablets.

is very liberal and possibly excessive; yet, with this latitude, an unduly large number are found wanting. It would seem that greater care must be exercised in the manufacture of this form of medication if its time-honored claim for uniformity of weight and dosage is to be maintained.

A review of the figures in the tables shows that in a large proportion of cases the variation is about as much above as below the average. If, therefore, a number of tablets are taken for analysis, as is commonly the case, it should be found that they average the proper amount of medicament. Consequently if a patient is given a number of tablets daily he will receive the intended per diem dose. This is not ideal or scientific medication. Before accepting the conclusion even on this basis, however, let us examine the premises. It is estimated that the average tablet contains the declared amount of medication. Fortunately, the correctness of this assumption can be established by a chemical analysis in a large number of cases.

CHEMICAL ANALYSIS.

Available information on the chemical analysis of tablets is meagre. Comparatively few analyses are recorded in the literature. All chemists conversant with this industry, however, hold that a 10 percent variation above or below the amount claimed to be present is ample for the vast majority of tablets and that only in exceptional cases should this variation reach 15 percent. Tablets containing volatile agents are not considered in this general conclusion.

The earliest chemical analysis of tablets with results recorded was made by Parry and Estcourt, in 1894. Four years later O. Liebreich had some analyses made of tablets. The results obtained by these workers are shown in Table 4.

*Liebreich, O., Ther. Monatshefte, 1898, 12: 476-7.

A summary on a percentage basis of these results shows the following:

	Variation greater than			
	10 Percent	12 Percent	15 Percent	20 Percent
	<i>Percent</i>	<i>Percent</i>	<i>Percent</i>	<i>Percent</i>
Parry and Estcourt.....	41.	27.	4.5	4.5
Liebreich	0.0	0.0	0.0	0.0

These results clearly indicate that the tablets examined by Parry and Estcourt vary unduly in many respects. The fact that these observations were made nearly twenty years ago should be taken into consideration. The analytical data obtained by Liebreich show that the tablets examined by him were very satisfactory. In not a single instance was there a variation of as much as 10 percent from the amount declared. This is an excellent showing, particularly in view of the fact that the tablets were made and analyzed fifteen years ago. All will concede that improvements in machinery and in manipulation, as well as along other lines, have been made since then.

TABLE VI.—*Results of the Analyses of Tablets by Pouchet.*⁶

Quinine hydrobromid.....	.030	.0292	—2.7
Sodium and caffen salicylate:			
Caffen0164	.014	—14.6

Although the results recorded by this observer are meager, they are included in order to make the data on this subject as complete as possible.

In 1899 J. E. Groff published an article entitled, "Examination of Tablet Triturates as Found in the Markets."¹ This worker examined tablets of calomel, mercuric iodid, morphin, and corrosive sublimate, as well as samples, of 1/60 grain strychnin sulphate. The strychnin sulphate, mercuric iodid, and corrosive sublimate tablets were found to be as represented, as were also the 1/10, 1/8, 1/4 and 1/2 grain morphin sulphate tablets. In one case doubt is expressed as to 1/8 grain morphin sulphate tablets. All of the calomel tablets contained either an excess or an insufficient amount of the drug. A careful reading of this article gives the impression that the methods used in making the determination and the form in which the results are expressed are unsatisfactory and vague.

The next systematic work was done nearly ten years later, when G. Frerichs² examined a number of pyrenol tablets. The results recorded by him show that the tablets he examined were, to say the least, of a very unsatisfactory character. In every instance the amount of chemical found was much less than the amount

⁶Pouchet, Gabriel, *Ann. de Pharm. Louvain*, 1898; 4: 375; *Abstr. Apoth. Ztg.*, 1899; 14: 179.

 THE BEST CO-OPERATION.

It is possibly an old-fashioned and out-of-date theory, but until I learn of stronger reasons against it than any I have yet heard, I shall hold to the faith that the best co-operation, and that which will serve the drug trade as a whole, is that wherein the manufacturer, the jobber and the retailer, while co-operating within their respective classes for their own profit, shall also co-operate, honestly and heartily, with each other for the welfare of all.—J. H. Beal.

Section on Practical Pharmacy and Dispensing

Papers Presented at the Sixty-First Annual Convention

PHYSICIANS AND PRESCRIPTION WRITING.

R. H. NEEDHAM.

In discussing this question, I shall confine my remarks to the prescriptions found in drug stores, not those models selected from text-books. I will not consider those orders for medicines which originated years ago, were used as formulas, and since, with a little elaboration and alteration, have attained the dignity of prescriptions.

Considering a prescription as an order for drugs or medicines to be compounded and dispensed, and the order to have been written by one who understands the practice of medicine, we would have in mind an order conforming in most its details, to a model prescription. I regret that such prescriptions are the exception, though, as time goes on, the number of more uniform and perfect prescriptions shows an encouraging increase.

The errors I shall criticise are the ones most commonly made, viewed from a pharmacist's standpoint. There are many others viewed from the therapist's standpoint that justly deserve criticism, though it might not be considered within my province to present the same.

Many prescriptions are offered to the dispenser which bear no heading or name, to give the pharmacist a clew as to sex, age or for which one of the family the medicine is intended. We understand that false ethics have rather decreed that those suffering from venereal diseases should not have their ailments advertised to the world, by placing their names upon prescriptions, but I wish to state that the druggists merit just as much confidence, in this respect, as the physicians. Dispensary experience has taught me to insist upon the name and the age of the patient being given, for, if quite young or very old, we absolutely need the latter, particularly, in checking dosage.

The next point I wish to take up is the inscription. In school and in the best text-books we are taught, that a model prescription should contain,—a base, an adjuvant, a corrective and a vehicle or diluent, though a prescription *may consist* of but one ingredient. In teaching this subject to students I try to impress the importance of keeping in mind this model, and deviations from it can readily be made. We regret that so many of the prescriptions to-day, show absolutely no earmarks of the prescriber having ever been taught in such a manner. Too many prescriptions show a tendency on the part of the prescriber to "shot-gun" the disease, not by ordering twelve or more ingredients for the prescription, but to provide several drugs for emergencies which might arise during the prognosis

of the disease. The drugs prescribed frequently show a lack of knowledge as to their action in normal or pathological conditions, whether secondary or primary in their action.

As one old physician expressed it, he preferred to always shoot with a rifle and to get what he shot at, therefore he gave calomel in 4 to 10 grain doses with soda only. After all, our old doctor was not far wrong and he usually obtained results.

I submit to you an example which will illustrate another point I wish to make,—the question of solubility. A prescription is frequently written, by a number of physicians, calling for sodium bi-carbonate, sodium benzoate and benzoic acid, in aqueous solution. Sometimes hexamethylaniline replaces the sodium salt. When complaint was made of the incomplete solution of the chemicals and the explanation was offered that the sodium benzoate and the benzoic acid were not in order, retort was made that the case demanded them so they were prescribed. The prescriber might think that "shot" was required, yet complete solution could not be effected unless there was chemical re-action. Another instance brought to my attention was the prescribing of creostal with acacia and cinnamon water to make an emulsion. In whatever manner this prescription was prepared, it would turn pink upon standing, although the druggist could have avoided the color-trouble by gently warming the creostal before emulsifying, or by adding a little expressed oil of almonds. The physician refused to allow the patient to take the medicine, even after seeing it compounded. I might add that the physician was well-educated, and an instructor in the practice of medicine in a medical college. The pink color lost the druggist that physician's business, and similar color changes often make trouble owing to the ignorance of the prescriber. I would suggest that a "sticker" or small label, be placed upon such preparations as are liable to color-changes; these stating that any color-change occurring in the preparation will not alter its medical effects.

The days of "shot-gun" prescriptions are not over, as many are written which contain two or more proprietaries, these, in turn, having from three to six ingredients giving a total of ten or more drugs and some of them making most unsightly preparations.

The so-called Latin of our prescriptions cannot be called Latin, as the tendency is to abbreviate everything that can be Latinized, and when the Latin name is not at hand the English name is given. I fear this habit is due first, to a lack of knowledge of medical Latin, and secondly to indolence and carelessness. There is little or no excuse for scratching and blotting figures and signs. It has always been the belief, that if the practitioner could not read a prescription after it was "cold," that there is always one who can read it, the poor long-suffering druggist. To receive a well-written, Latinized prescription, is a source of inspiration and delight to any pharmacist, and he would be a knave indeed who would not send out the prescription with as much care and elegance as the order was written.

What are the remedies to be applied to correct some of these ills? After close observation of these particular evils, I unhesitatingly answer, *better and more thoro education both for the druggist and physician*. There is too great a difference between them in this respect, so much so that the physician with his more

complete education, looks down upon the druggist, with less education and his commercial business, as one who should not pretend to proffer advice nor be consulted on matters of prescription-writing or compounding. There are some great faults existing in our system of medical education and I shall attempt to point out one or two. In the schools to-day, prescription-reading is taught to pharmacy students, while prescription-writing is taught to "medics." The former is apt to hold to his instruction, for his mind is not diverted during his course in school. The "medic" is so extremely anxious to prescribe that he rapidly skims over the fundamentals of prescription-writing, beholding a vision of office-days, when he shall write prescriptions by the dozen. When he reaches his third and fourth year's work, he has completely forgotten the fundamentals, but has acquired a host of formulas. I regret to state that the instructors pay little attention whatever to set rules for formulating prescriptions, but write with dash and rapidity, abbreviating everything possible. There is a lack of exactness and precision, little or no attention paid to those small details which go to establish the fundamentals of prescription-writing. After all this, what opportunity has the druggist to gain the physician's confidence, that he may discuss a prescription with him, as to incompatibility, etc.?

I trust that the education of the future druggist will be so complete along this line, that he will have a more complete knowledge of pharmacology and therapeutics. Then, perhaps, it will be with all as with a physician friend, who writes or telephones his prescription "*secunden artum*" (!) for the subscription. When asked why he wrote thus, he replies that he has full confidence in his man, and believed that such a pharmacist could dispense a better prescription in every way, if given the due measure of liberty and confidence he deserved. It would appear then that if we can succeed in attracting the notice of medical instructors and direct their attention to this flaw in medical education, we would be in a position to expect better-written prescriptions. Give our pharmacists a more complete education that they may feel free to bring to the attention of practitioners the necessity of a better knowledge of the fundamentals of prescription-writing. Such a state of affairs would certainly be conducive to better and more friendly relations between druggist and doctor and we predict that the prescription-business will be increased proportionately.

DISCUSSION.

Doctor Fantus said he was sure he had profited by this paper, and voiced the same wish as the author of the paper, that more of the practicing physicians would get the advantage of proceedings of this kind. He pleaded for charity for the doctor, who wrote his prescriptions very often under the most trying circumstances—circumstances that tested the nerves of the strongest; when he had, perhaps, half a dozen crying men, women and children around him, with the patient in the most desperate condition. Under such circumstances, the physician was not likely to recall all the things that should go into a prescription, such as the writing of the patient's name, etc. He did not mean that the physician should not do these things as precisely, and with as much precaution, as the druggist should fill the prescription; he only meant to refer to the difficulties surrounding the physician at times. He, sometimes, said to his students that prescriptions should be a good deal like a bank-check, and that the same care should be exercised in writing them; in fact, that greater care should be taken. There was no question but that the highest degree of precaution should be used, in order that medicines might be administered scientifically, and be made more pleasant and efficient. He

wondered, sometimes, whether something might not be gained by making an investigation regarding the qualifications of applicants to practice medicine in prescription-writing, as an end to bettering the deplorable conditions that sometimes existed. If in order, he said he would like to move that a committee be appointed to make such investigation, and ascertain the extent to which prescription-writing was taught in the medical colleges of the country, and the extent to which medical examining-boards inquired into the thoroughness with which candidates had been prepared for prescription-writing.

This motion was seconded by Mr. Needham.

Mr. Fennell said he hoped this motion would not prevail, as he thought the pharmaceutical profession had its hands full in investigating the colleges and other teaching institutions of pharmacy of the country, and seeing that *they* did the proper thing, without invading the domain of the medical profession. He did not think it was within the province of this association of pharmacists to thus undertake an investigation of the medical profession.

Mr. Nitardy suggested that Doctor Fantus, who had so ably put this proposition before the Association, might, as a member of the medical profession, be appointed a committee of one on this subject. It could then be made with fairly good grace, and he could report to this Section at some future time, say, next year. Then the members would be in a position to act, provided the suggestion met the approval of Doctor Fantus, after thorough consideration.

Doctor Carter said that, as a practicing physician, he desired to support the recommendation made by Doctor Fantus. No one appreciated the inability of the average physician to write the prescription properly, more than the physician himself. He had been brought in contact with both juniors and seniors in this work, and realized this as one of the greatest weaknesses of the medical profession. He had been helped more by the daily assistance of pharmacists, who filled his prescriptions, than in any other way, and he thought a great work could be done by pharmacists in training the younger physicians in this respect. This was a particularly good field for labor with young physicians beginning the practice of their profession. It would do away with the prescribing of proprietary and special formulas, which was being constantly forced upon the younger physicians. As a practitioner of medicine, he said he would be glad to support the motion made by Doctor Fantus.

Mr. Mayo said that he, too, would like to support the motion made by Doctor Fantus. A physician was not a god, nor even a demi-god; he was a mortal man. He made errors, and the pharmacist made errors. This was entirely an impersonal thing, and he thought it was wholly within the province of the pharmacists of the country to ascertain why it was that they received prescriptions which were such a discredit to the medical profession. They would be doing the medical profession a great service if they could point out these defects in their medical curriculum.

Mr. Gordon wanted to know, if this committee was appointed and made report at the next meeting, what it was proposed to do with that report. Mr. Mayo sententiously replied, "We sha'n't suppress it. The disposition of that report will lie with the body to which it is made."

Mr. Alpers said that medical schools had devoted a great deal of attention to this work of prescription-writing in late years, and he believed that the young medical men of the day were competent to write prescriptions. There were a great many physicians in the country who were deficient in this respect—who had not been taught to write prescriptions when they went to school. All pharmacists knew this, and the physicians knew it, too. It was to be regretted that it was so. He personally knew it to be a fact that physicians sometimes hesitated to write prescriptions, because they were in doubt about the proper names of things, and they would go home and fix up the prescription themselves. The desired end could only be brought about by gradual improvement in both pharmaceutical and medical colleges. If the pharmacist complained that the physician did not understand Latin, he was liable to have the physician come back and say: "How many of you understand Latin?" It was necessary for both the medical and pharmaceutical colleges to first look into the entrance requirements. The science of chemistry and other allied sciences was international, and should have a nomenclature to be understood by all nations. The only language fitted for such work was the Latin language. Every physician, therefore, should be familiar with the Latin language.

before he undertook the study of medicine, and the same thing applied to the pharmacist. He could see no objection to having knowledge as to whether a medical college in New York or California taught prescription-writing, but he could see no benefit to be derived from such an investigation, beyond the securing of a lot of statistics for publication, and, personally, he did not agree with this tendency. He believed the physician and pharmacist should be, from a scientific and professional standpoint, intimate friends in every respect. He had found it better policy not to allow a continuous enmity between the two professions. A great many physicians were willing to write prescriptions and trust to the pharmacists, who had the proper education, to correct their Latin. Very often the physician did not know the exact degree of solubility of certain articles, but he said "make a solution," and left it to the pharmacist, and it would be bad taste for the pharmacist to conclude from that, that the physician was a fool.

CALOMEL SUSPENSION.*

F. W. NITARDY.

The object of this paper is not, as you may assume from the title, to explain how to produce a calomel-suspension, even though this will be done incidentally, but it is written to relate an experience which may apply to other substances precipitated from solution, and may, in that capacity, prove of interest or value.

Some years ago, a "beauty doctor" came to me with the request to duplicate for her a certain liquid face powder. I had seen the analysis of this preparation published, and I had confirmed same by my own analysis. Its composition was calomel and water.

I found that the calomel on the market was too coarse to be used for this purpose, so I determined to make a finely divided calomel by precipitating same from a dilute solution. I had no difficulty in obtaining calomel of the desired fineness or even finer, but found that when this was mixed with water, the precipitate would invariably coalesce into a curd, and then rapidly settle out. I tried to overcome this tendency in various ways but failed.

The "beauty doctor" was not satisfied with this preparation and as she left the city soon afterwards, I paid no further attention to the mixture, a sample of which still remained in our laboratory.

Some weeks later, I thought I would add some mucilage of Acacia to the mixture and see how much of a mucilaginous substance would be necessary to prevent this curdling of the precipitate. So, I added 5 percent, by volume, of mucilage acacia, and shook the mixture well. I found this was sufficient to bring about the desired result, possibly more than sufficient. To determine this, I allowed the mixture to stand until the calomel had settled out, decanted a portion of the supernatant liquid and replaced it with water. It still remained in the desired condition, so I repeated the operation and kept on repeating it, until all the mucilage had been washed out of the precipitate, which no longer coalesced in curds when suspended in water. In this condition it remained suspended in the water.

To illustrate this clearly to you, I have brought a sample of the suspension, half of which has been treated as above outlined.

*Section of Practical Pharmacy and Dispensing, A. Ph. A., Nashville, Aug., 1913.

As was stated in the beginning, this paper was written to illustrate the change in the behavior of a precipitate under this treatment, for I doubt if a preparation like this calomel-suspension would have any practical value for pharmaceutical purposes, unless it be as a liquid face powder.

DISCUSSION.

Mr. Dunning said that he thought probably the explanation of the effect that Mr. Nitardy had procured was, that the mixture is somewhat of a colloidal nature, and he thought possibly he would have gotten the same results if he had used some other colloid. Gelatin perhaps might do. It might be that the bichloride might interfere in case of gelatin. However, if some suitable colloid could be found and dissolved in water in which the precipitate is to be formed, it would probably require only a trace and good results might be obtained. The calomel would be thrown out in very fine state of sub-division, and would remain in that state, and then the precipitate could be washed with a very weak solution of colloid.

Mr. Raubenheimer stated that a very surprising affect could be had by adding a small amount of gum arabic or mucilage to both of these solutions, mixing them together, and it would produce a very clear solution, with no precipitate.

Mr. Dunning's reply to this suggestion was, that it was quite possible, instead of being able to get a precipitate, one might not be gotten by following his suggestion. While a precipitate may be formed, it might have the characteristics of a solution, and this trouble, he thought, would probably be overcome by using a minute quantity of colloid, but this could only be determined by experiment.

Mr. Nitardy said that he would like to state that the fineness of precipitate in both bottles was exactly the same. This could be proven by examining the precipitates under a high-powered microscope. There was a particular tendency, which might be called molecular cohesion, which caused them to come together. After they had cohered, they settled out more readily. He recognized that there might be other ways of accomplishing these same results.

Doctor Fantus said that, just as a suggestion, he was wondering whether it might not be possible for it to be a question of electrical change, resulting in a coalescence of the particles of calomel.

Mr. Wilbert thought this was another illustration of "How little we pharmacists know." They thought they knew a lot, until they came to look into a solution or a mixture, such as those which had been seen here, and then realized it was all based upon presumption, and not upon knowledge.

Mr. Dunning said that the reason that pharmacists knew so little about conditions of this kind was, that no one knew much about colloid-solutions and colloidal-conditions, and he was positive that whatever might be the actual conditions here, it was of a colloidal-nature, or had to do with the colloids.

Mr. Windolph said the author of the paper had said that he did not know that it would matter much, since the suspension of calomel was probably useless for any other purpose, than as a liquid face-powder. He thought if there could be produced a preparation of calomel, that would hold the chemical in suspension, a valuable addition would be had to *materia medica*. The most important objection to an ointment in some of these skin lesions, was the fact that grease prevents the elimination of certain matters which should be removed; and a wash which had no greasy substance in it, and which would distribute the calomel properly, he was quite sure would find a place in many cases of eczema and such diseases.

Mr. Nitardy thanked Mr. Windolph for the suggestion made. He said that, for fear some of the members might have noticed a difference between the two bottles exhibited, aside from those he had stated, he wished to mention one thing he had forgotten, viz: In one of the preparations he had used orange-flower water, whereas in the other he had used plain water. That was done to see if the calomel would discolor in rose-water or orange-water.

A GOOD FINISH FOR PRESCRIPTION AND LABORATORY TABLE TOPS.*

F. W. NITARDY.

The prescription case or laboratory table top cannot be satisfactorily finished by the usual methods. Too many things that affect or destroy the average finish, are likely to be spilled upon them and sooner or later the top becomes unsightly. Some fixture-manufacturers furnish these tops without any finish whatever, but these offer no particular advantage as they soon become stained and no amount of scrubbing will keep them sightly.

While serving my apprenticeship in a country town in southern Minnesota, the firm invested in new fixtures and the prescription-case came with an unfinished top. My preceptor, Mr. John B. Christgau, applied a chemical which proved very satisfactory. It did not discolor nor was it in any way affected by acids, alkalis, or alcoholic liquids, etc., that might be spilled on it, and it looked as good after 10 years service as it did when first finished.

I have used this finish extensively since and found it equally satisfactory, but as I have not seen it used by others, nor its formula in print, I feel that it might bear publication, in view of its very serviceable and practical character. It may be used on new or on old finished surfaces, providing in the latter case, the wood is freed from the old finish by varnish-remover or other means.

To apply the finish proceed as follows:

Thoroughly clean the wood by scrubbing with soap and water. Allow it to dry.

Prepare a saturated solution of potassium chlorate, heat to boiling, and apply to the wood while hot, so that it will penetrate the fibre. When dry, apply a second coat, in the same manner. Now prepare a 20% solution of copper sulphate and apply boiling-hot, after the former has dried, allowing the wood to become well saturated and taking up any surplus liquid remaining after 10 to 15 minutes, so that no appreciable crystalization takes place on top of the wood.

When this is dry, apply a solution made by dissolving 90 parts by volume of aniline oil in 60 parts by volume of hydrochloric acid, diluted to 500 parts with water, and allow that to well penetrate the wood. Let this coat dry about six hours or over night, then apply a heavy coat of hot, raw, linseed oil. Allow to stand six hours or over night and scrub well with soap and water until all surplus color has been removed, that is until the water stays clean, now allow to dry and rub down well with linseed oil, applying several coats (a day or two apart) if necessary to completely fill the pores of the wood.

This gives a deep-black finish, with a slight gloss, which can be kept in perfect condition by an occasional scrubbing with soap and water and a subsequent rub-down with linseed oil.

The finish will not affect wood covered with oil, wax, varnish, or other substances, that do not permit the penetration of aqueous solutions, but will to a cer-

*Section of Practical Pharmacy and Dispensing, A. Ph. A., Nashville, Aug., 1913.

tain extent stain a light colored finish, especially white enamel, so care should be used in its application lest one might discolor adjoining woodwork.

DISCUSSION.

Mr. Raubenheimer expressed the opinion that this was a good thing, and he knew of one of the teachers in his school who used this process.

Mr. Becker called attention to the fact that a similar formula was published a few years ago by Bausch and Lomb, in the Journal of Applied Microscopy and Laboratory Methods, the title of the paper being "An Acid-Proof Table-Top," by Pierre A. Fish, New York State Veterinary College, Vol. VI, No. 3, March, 1903, pages 2211 and 2212.

Mr. Dunning said if the discussion of glass counters was in order he would like to say that in his establishment they had not had the most satisfactory experience with them. They were a most excellent medium for breaking glass things, as they had no elasticity. They had remodeled their main store, and put in solid mahogany, unvarnished counter-tops.

Mr. Wilbert suggested that if the pharmacist would take an ordinary pine board and saturate it with paraffin he would find it would make a fine table-top.

LIQUOR MAGNESII CITRATIS.

J. LEE BROWN, PH. G.

So much has been written about Solution of Magnesium Citrate that one would think the last word had been said on the subject, yet its preparation still continues to be a source of trouble to many pharmacists. A great many formulæ and modifications of the U. S. P. process have been proposed, so I take the liberty of presenting a method that has proven entirely satisfactory in my experience for many years, and that has made "citrate" one of our best sellers. I use the U. S. P. formula with a few modifications as follows:—

Magnesium Carbonate U. S. P.	180 gm.
Citric Acid	396 gm.
Syrup	720 cc.
Spirit of Lemon	10 cc.
Potassium Bicarb.	12—2.5 gm. Tablets
Water to make 12 bottles of solution.	

Place the magnesium carbonate in an aluminum vessel of about 4 L. capacity which contains about 2 L. of water. Now add the citric acid. Let stand till effervescence ceases and complete solution results. Place the vessel containing the solution, on an open flame and raise to the boiling point and allow to boil a few moments. Add the spirit of lemon and filter while hot through a well-wetted white filter, contained in an aluminum funnel. When the solution has all passed, wash the filter by passing about a pint of boiling water through it. Now add the syrup and divide the liquid accurately between twelve patent-stoppered citrate bottles. Fill the bottles nearly full with water, drop in each a 2.5 gm. tablet of potassium bicarbonate and stopper immediately. I have found it unnecessary to use distilled water, as the water in my locality is almost entirely free from any mineral contamination or organic impurities. The whole process can be completed in a short time, with very little attention. Filtering at

the boiling temperature, is completed in about ten minutes, while filtering cold, according to the U. S. P. method, requires two hours at least, and a perfectly clear and bright filtrate would not result as with my method. I have kept this solution, made as above, in the store at ordinary temperature for two weeks, perfectly clear and free from the slightest precipitation. I do not favor the proposition to use magnesium oxide, instead of the carbonate, as the oxide is so prone to change in ordinary keeping, absorbing CO_2 and changing to the carbonate. Solutions made from it would vary considerably in magnesium-content.

DISCUSSION.

Mr. Hynson exhibited a sample bottle of magnesium citrate as put up by his firm, and passed it around among the members. He said he used a green bottle for this purpose. For years, he said, he had tried to change the color of the wrapping-paper used in his store, but had never been able to do so, as he had never been able to impress upon his employes that anything but white was the proper color. A few years ago he had bought in the district around Baltimore, twelve bottles of magnesium citrate, expecting to find magnesium sulphate in them; but every one was correct as to contents, while each was bad as regarded pharmacy. Many druggists used their soda-water lemon syrup, but hardly one of the samples contained enough carbon dioxide to preserve the preparation and to make it pleasant. One of his customers had informed him upon a certain occasion that he had bought solution of magnesium citrate, and the bottles had turpentine in them—but this was several years ago.

Mr. Perry said he, at one time, had made citrate of magnesia in fairly good quantities, and always according to the process of the pharmacopœia. He had always sterilized the water and container. One day one of his men had suggested the idea of making a window exhibition, and this was done, with the result that his sales of citrate of magnesia increased 150 percent. He had several stores, and he "passed it around" to all of his stores.

In reply to a question by Mr. Nitardy as to whether he was accustomed to take the bottles back after the patient had used the contents, Mr. Hynson replied that he did not, as a rule, though this rule had an exception where he knew the party, and knew he had bought the citrate of magnesia from his store.

The Chairman stated that he had presented a paper on this subject at the Boston meeting, in 1911.

Mr. Becker said he would like to say, in connection with concentrated solution of magnesia, that he had found three times the U. S. P. strength to be a very convenient way of dispensing citrate of magnesia. He also found that it kept very well.

Before a man can reach the state of "knowing" he must train his mind to the best thought in his profession or business. The Present is always an improvement upon the Past. Unless you keep step with the present, you are certain to find yourself an incompetent laggard in the future. The men at the top "know" the exact forward movement in their chosen vocations. They can never find out enough about their work. To know and apply your knowledge is to succeed. To know that we know what we know, and that we do not know what we do not know, is true knowledge.—*The Pacific Druggist*.

Contributed and Selected

A NOTE ON THE VALUE OF PRESERVATIVES IN SYRUP OF IRON IODID.*

GEORGE M. BERINGER, PH. M.

In the U. S. P. Eighth Revision, Diluted Hypophosphorous Acid, to the extent of 20 cc. to 1000 gm., is directed to be added to this Syrup as a preservative. Several of the foreign pharmacopœias direct the use of organic acids for the same purpose; the Austrian Pharmacopœia directing 0.1 percent of Citric Acid, the Swiss Pharmacopœia, 0.05 percent of Citric Acid, and the French Pharmacopœia, 0.1 percent Tartaric Acid. The German, the British, the Danish, the Swedish, and the Italian Pharmacopœias, do not direct any preservative, dependence being placed upon the use of sufficient sugar.

In order to test the relative value of these preservatives, six samples of Syrup of Iron Iodide, were prepared on October 15, 1913. In the preparation of all of these, the official process, manipulation and percentage of iron, salt and sugar were carefully followed. These samples were preserved in my laboratory, and not exposed to direct sunlight, for several months. On December 18th, their condition was observed and noted. Subsequently, these samples were deposited with Chairman Remington and preserved in his laboratory, with the other pharmacopœial samples, until a few days ago, when I obtained them for observation of the further changes that had taken place. In the tabulation below, the appearance on these two dates of each sample is noted:

No. 1.—Prepared by the U. S. P. formula, but without preservative.

On December 18th, this sample was slightly yellow. It is now of a pale green color, and appears to be in perfect condition.

No. 2.—U. S. P. VIII, formula without any variation. On December 18th, this sample was very pale, but perfectly clear. It was noted that the green color had gradually faded and the sample was much lighter in color than when first prepared. This is in accordance with the previous observations on this formula.

This sample is now of a light yellow color and there is evidence of some change in the sugar; the change that we have commonly considered as "caramelizing," which takes place in the presence of Hypophosphorous Acid.

No. 3.—Formula of the U. S. P., with the addition of 0.05 percent of Tartaric Acid. This sample, on December 18th, had assumed a distinct yellow color. It has now faded, until it is almost colorless.

No. 4.—Formula of the U. S. P., with 0.1 percent of Tartaric Acid. On December 18th, this sample had retained a light green color, about the same

*Read at the meeting of the New Jersey Pharmaceutical Association, Lake Hopatong, June 17, 1914

tint as when first prepared. It now shows no change and appears in perfect condition.

No. 5.—Formula of the U. S. P., with the addition of 0.05 percent of Citric Acid. On December 18th, this sample was of a very light green color, and preservation appears to have been perfect. It now shows no further change.

No. 6.—Formula of the U. S. P., with the addition of 0.1 percent of Citric Acid. On December 18th, this sample had retained its original pale green color and at this time preservation appears to have been perfect.

Conclusions:—If Syrup of Iron Iodide is carefully made, with the proper amount of sugar, no preservative whatever is needed. However, to overcome the careless manipulation on the part of some druggists, it has been deemed advisable to add a preservative. Hypophosphorous Acid has the advantage of a reducing value which is not possessed by the organic acids suggested for this purpose. It has, however, the disadvantage that, in the strength directed, it will act upon sugar in strong solutions and darken the syrup. This could be overcome by substituting Glycerin for a portion of the Sugar directed in the formula.

DONT'S IN PHARMACY.*

OTTO RAUBENHEIMER, PHAR. D.

From the experience, and quite especially from the mistakes and failures, of others we can always learn. This also holds good in Pharmacy and is my excuse for this paper.

These "Don'ts in Pharmacy" are taken at random from my lectures in the Department of Pharmacy of the University of New Jersey, and have been highly appreciated by my students. No doubt some of these "Don'ts" will be helpful, even to some members of a State Pharmaceutical Association.

In the opinion of the author it is quite as essential,—equally important,—to know how *not* to do it as it is to know how to do it. Let the following maxim be the motto of every pharmacist:

"Do it well and do it right!"

In the presentation of the present paper, the author has made an attempt to classify the "Don'ts" as follows:— General, Chemicals, Galenicals, Strength of Preparations, Dispensing, and the Prescription Department.

General.—First of all, don't hide your copies of the U. S. P., N. F., Dispensatories and other standard pharmaceutical works, but keep them in a prominent place so that you can readily consult them. A druggist who cannot lay his hands on the Pharmacopœia is like a minister who cannot find his Bible.

Don't get along without a pharmaceutical library, but collect and select the standard works on pharmacy, chemistry, materia medica, pharmacognosy, etc., which serve as reference books in the daily practice of the pharmacist. As a

*Read at the meeting of the New Jersey Pharmaceutical Association in Lake Hopatcong, June, 1914.

rule, the library, or the non-existent library, of the average druggist, is a disgrace to pharmacy.

Don't fail to subscribe for, and to diligently read, at least a few pharmaceutical journals, in order to keep posted on the progress of pharmacy.

Don't neglect to become a member and an active member of your local pharmaceutical society, your state pharmaceutical association and also such national organizations as the A. Ph. A. and N. A. R. D.

Don't take an apprentice and neglect to instruct him properly in pharmaceutical *technique* and practice.

Don't forget to send this apprentice to a good college of pharmacy, where he will receive a proper education in the theory and practice of pharmacy by competent teachers.

Crude Drugs.—Don't neglect to place occasionally a little chloroform on a pledget of cotton within the containers of such vegetable and animal drugs, as are prone to be infected with insects, such as Lovage Root, Raspberries, Huckleberries, Linseed, Burdock Root, Ergot, Cantharides, etc.

Don't dispense, or utilize for galenical preparations, the following, when more than one year old: Ergot, Aspidium.

Don't neglect to separate and to reject the seeds from Coloyanth, before using this drug in a preparation, because the seeds are inert and they contain fat or oil which are objectionable in pharmaceutical preparations.

Don't use the entire peel of Sweet Orange, but only the outer thin rind (the so-called "Flavedo"), which is rich in oil-cells and free from tannin or bitter principles.

Don't dispense the following drugs and preparations, except when properly aged, as directed by U. S. P. or N. F.:— Cascara (1 year), Frangula (1 year), Tincture of Ferric Chloride (3 months), Tinctura Ferri Chloridi Aetherea, N. F., (first after being decolorized and then placed in the dark to assume a golden yellow color).

Chemicals.—Don't use technical chemicals for medicinal purposes, as they do *not* comply with the U. S. P. standards and very frequently contain inert, in fact, poisonous substances.

Don't keep chemicals which readily absorb moisture in a damp place. Examples are too numerous to mention and include all hygroscopic and deliquescent chemicals. I might call attention to *one* in particular which is frequently kept in cellars and which consequently spoils, namely, Chlorinated Lime.

Don't expose certain chemicals to the action of direct lights. By such exposure Phenol and Resorcinol becomes pink or even red; Alkaloids are discolored; Iodides, especially Ammonium Iodid, liberate free Iodine; Silver Salts, Calomel and many other chemicals darken, owing to the formation of oxide; Santonin turns yellow; Naphthalene and Beta-naphthol become discolored; Sulphurous Acid is oxidized to Sulphuric Acid; Chlorine and Bromine Water form Hydrochloric or Hydrobromine Acid, respectively; Ferric Salts will be reduced to Ferrous Salts, and Mercuric Salts to Mercurous Salts; Compound Syrup of Hypophosphites become decolorized; and volatile oils become terebinthinate.

Among the other chemicals affected by light are Benzoic Acid and Benzoates,

Salicylic Acid and Salicylates, Hydriodic, Hydrobromic, Hydrocyanic, Nitrohydrochloric and Trichloroacetic Acids, Amyl Nitrite and others Nitrites, Chloroform, Bromoform and Iodoform, and many others.

Don't expose *Ferric* Salts and their preparations to the light, but keep them in dark amber-colored bottles.

Don't keep *Ferrous* Salts and their preparations in the dark, but expose them to the light, for instance, Syrup of Ferrous Iodide.

Don't expose the following to the action of the air, as they readily absorb CO_2 : Lead Acetate and Solution of Lead Sub-acetate; Ammonium Carbonate (forming Bi-carbonate); Calcium Oxide, Lime Water, and Magnesium Oxide, light or heavy.

Don't expose volatile chemicals, liquids or solids, as they will evaporate or lose strength.

Don't expose chemicals which effloresce to the action of dry air. In this list all crystallized salts are included.

Don't dispense the following chemical and pharmaceutical preparations, except when recently prepared: Diluted Nitro-hydrochloric Acid, Sulphurous Acid, Chlorine Water or Compound Solution of Chlorine, Creosote Water, Infusion of Digitalis, Solutions of Magnesium Citrate, of Ammonium Acetate, of Iron and Ammonium Acetate, of Potassium Citrate, of Sodium Citrate, Chalk Mixture and Compound Iron Mixture.

Don't neglect to have on hand the two (2) solutions, ready to be mixed, to form the Arsenical Antidote of the U. S. P. This should most certainly be done in every well-regulated pharmacy, as many a life might be saved, especially during the summer when poison fly paper is extensively used.

Galenicals.—Don't permit Medicated Waters to freeze, as it will destroy their aroma. This is especially true of imported Triple Orange Flower and Rose Water, which are frequently purchased in original 10 liter demijohns. It is for this reason that U. S. P. IX will include a caution notice *not* to allow Medicated waters to freeze.

Don't expose bottles of Hydrogen Peroxide to direct sunlight, as is frequently done in window-displays by druggists and other store keepers. No matter how attractive this window display may be, the H_2O_2 will gradually turn into H_2O , which can be obtained much cheaper from the hydrant or faucet.

Don't prepare Liquor Calcis by mixing together a pail of hydrant-water and a lump of ordinary mason's lime by means of a broom handle, but use the very explicit U. S. P. process, employing Calcium Oxide and Distilled Water.

Don't filter Lime Water, as filter paper will absorb, or more properly adsorb, part of the lime, and, also, because some of the calcium hydroxide will be converted into calcium carbonate by exposure to air. Lime Water should be syphoned or decanted as directed by Pharmacopœia.

Don't give away Lime Water, or any other cheap galenical preparation! Make these preparations according to U. S. P. or N. F., and charge for them!

Don't cheapen any medicines by giving them away!

Don't use Fluidextract of Belladonna *Leaves* in the preparation of Linimentum Belladonnæ, but use Fluidextract of Belladonna Root, which contains 0.4 percent

of mydriatic alkaloids, while the U. S. P. standard for Belladonna Leaves is only 0.3 percent and very likely the *unofficial* fluidextract contains the same percentage of alkaloids, if not less. I am informed by manufacturing chemists that they sell five gallons of *unofficial* Fluidextract of Belladonna *Leaves* to one pound of the official Fluidextract of Belladonna *Root*. This, very likely, accounts for the fact that a great many pharmacists in New York State had to pay a penalty for shortage in the alkaloidal-percentage of Belladonna Liniment.

Don't keep Sweet Spirit of Nitre in a quart shelf-bottle about one-quarter full, as is frequently done in ordinary drug stores, but *do* keep it, as correctly ordered by U. S. P., in small, dark, amber-colored vials in a cool place, remote from flame or fire. The author is in the habit of storing this product in four-ounce glass-stoppered amber bottles.

Don't use *gray* filter paper, as it contains impurities and frequently traces of iron. Use *white* filter paper which is a pure article, even if it costs a *few cents* extra *per 100 sheets*.

Don't use *powdered* Asafetida to make Emulsion or Milk of Asafetida, but employ *selected tears*, which are free from inert substances.

Don't forget that Elixir Iron, Quinine and Strychnine Phosphates contains the salts as *phosphates* and about 1/60 grain of Quinine Alkaloid to one fluidram, while Elixir Iron, Quinine and Strychnine, N. F., contains the Iron as Citro-chloride, the Quinine as Hydro-chloride, and the Strychnine as Sulphate, the latter in the proportion of 1/100 grain to one fluidram.

Don't employ *Precipitated* Chalk when *Prepared* Chalk is ordered, because the latter possesses the decided advantages of being an amorphous powder which is more adhesive.

Don't store powdered or ground white or black mustard, or mustard-plasters in a damp place, as they will rapidly lose strength.

Don't keep Compound Licorice Powder and other compound powders in the cellar, as they absorb moisture and deteriorate.

Don't dispense Cerates and Ointments when rancid, because they are very irritating.

Don't neglect to keep Syrups, Mucilages, Honeys, in fact all preparations which are liable to turn sour, in a cool place, preferably in a refrigerator.

Don't dispense Biologic Products, Ferments and other limited preparations after expiration of date, as much injury to the health of the patients may result from the use of such preparations.

Strength of Preparations.—Don't forget that, according to the Brussels Protocol, an International Agreement was signed by which all potent tinctures are 10 percent in strength, and all arsenical preparations are 1 percent in strength, and that the U. S. P. VII was the first Pharmacopœia to adopt these new standards.

Don't forget that Pearson's Solution of Sodium Arsenate, N. F., contains only one-tenth the amount of Sodium Arsenate as the U. S. P. Liquor Sodii Arsenatis.

Don't forget that, according to this International Agreement, Diluted Hydrocyanic Acid contains 2 percent of HCN, and Cherry Laurel Water 1 per mille. HCN.

Don't forget that Mercurial Ointment U. S. P. contains 50 percent metallic mercury, while Blue Ointment only contains 33 percent Hg.

Don't neglect to fill foreign prescriptions or to make preparations of foreign Pharmacopœias according to their standards, as there is quite a difference, not only in physical and chemical characteristics, but also in strength.

Dispensing.—Don't dispense *Coaltar Creosote*, when Creosote is called for, as Creosote means *Beechwood Creosote*.

Don't dispense Crocus, when Saffron is desired, to be made into an infusion against measles, but dispense Carthamus.

Don't dispense Anthemis, when Chamomile is called for, especially by a foreigner who wants Matricaria.

Don't dispense Spiritus Aetheris Compositus, when Hoffmann's *Drops* are asked for by a German customer, as he wants Spiritus Aetheris, *not* the compound.

Don't dispense Petroleum Naphtha or Benzin, when Naphtha or "Nafta" is called for by a Scandinavian who wants Spirit of Ether.

Don't dispense Petroleum Benzin, when Benzine is called for by an English customer who wants Coal-tar Benzene or Benzol C_6H_6 .

Don't dispense *Boiled Linseed Oil*, in place of Oleum Lini.

Don't dispense the ordinary Turpentine for internal use, but the Rectified Oil of Turpentine.

Prescription Department.—Above all don't substitute, but dispense the articles which are prescribed and charge for same.

Don't hide your Prescription Department, but make it the most prominent feature of your store. Such signs as "*Drugs and Prescriptions in the Basement*" are a disgrace to professional pharmacy.

Don't make your motto "Cheapness and Quickness," in your Prescription Department, but much rather "Prescriptions Compounded Carefully and Conscientiously."

Don't run your Prescription Department without any or but very little apparatus and utensils, but have a complete outfit. No matter how expert the pharmacist is, he must have the necessary tools in order to turn out good work.

Don't convert metric weights and measures into the apothecaries' system; have a complete set of metric weights and measures, use these and thus avoid errors.

Don't neglect to properly number prescriptions consecutively and also to date them.

Don't forget to mark the price on each prescription in plain figures, as this will prevent unpleasant disputes with customers.

Don't file prescriptions by such an antediluvian method as a string or wire, but preserve them in a sanitary manner in a prescription book or still better, in the opinion of the author, by means of one of the up-to-date filing-cabinets.

Don't dispense ordinary water when distilled water is wanted.

Don't forget that *sterilized* water means *freshly boiled distilled water*.

Don't dispense solutions or syrups which are cloudy, but filter or strain them.

Don't forget that psychology still plays a very important part in medicine and

pharmacy. This is especially true regarding the prescriptions which you dispense.

Last, but not least, don't forget the motto: "*Cleanliness is Next to Godliness,*" and to this we might add, "*and is of the greatest importance in medicine.*" It will be a credit to your Prescription Department to display such a sign.

Conclusion.—Should this little advice on "Don'ts in Pharmacy" prove helpful to the members of the New Jersey Pharmaceutical Association, then it will be followed with a continuation of them at the next meeting next year.

Meanwhile permit me to give you just one more "Don't," which in my opinion is *the* most important one, viz.:

Don't be a "Jack of all Trades," but try and be a master of a profession, namely, pharmacy.

ADVERTISING A RETAIL DRUG STORE.*

ADOLPH H. ACKERMAN, PHAR. D.

In the olden times the insignia of the alchemist, the then time pharmacist, was the glass retort or the stone mortar and the pestle. Then, when several dispensers of medicine occupied the same town, they used different signs to inform the people of their own particular drug store. These signs, were, as a rule, taken from the animal kingdom, which was, at that time, the principal source of supply for drugs for the treatment of the sick. It was the apothecary shop of "The Snake," of "The Swan," "The Lion," or "The Scorpion," etc. Within our time and particularly in Continental Europe, pharmacies are even now recognized by these signs.

In our generation the colored window show-bottle can still be seen as the sign of the apothecary.

In these days, when the profession of pharmacy is subservient to that of the commercial aspect of pharmacy, this is no longer sufficient to inform the people of the various communities of the location and capacity of a drug store, so to-day the pharmacist is compelled to use all the means and arts of the advertiser, to inform the public in regard to these facts.

The daily papers are being used by the big chain drug-stores to reach the masses. Local papers, programs, and other organs, are being utilized by the community drug-store. This class of publicity seems to be about the only method of advertising which is understood as "Advertising" amongst the retailers.

If you gentlemen, however, will recognize that Advertising is Salesmanship, and Salesmanship is Advertising, and that the object of both are "Merchandising," you will then admit that the methods I point out to-day should all be classed as advertising and should have the same earnest consideration you give any other feature of your business.

Advertising is intended not alone to tell the people in your vicinity that your

*Delivered at the Annual Convention of the Massachusetts State Pharmaceutical Association, June 17, 1914, at Swampscott, Mass.

store is located at a certain corner, but it is also meant to get your neighbors' good-will and confidence in such a manner that he will voluntarily come to your store to make his purchases in your lines.

Any action you take which induces this good-will is Advertising.

Appearance: The looks of the front of your store, such as clean, fresh paint; neat, tidy awnings; readable, dignified signs, is Advertising. Many a beautiful window is spoiled by a weather-worn frame of dingy paint or a tattered, dirty awning. Your wood-work should be painted at least four times a year with one coat of paint. This will always keep it in a clean and slightly condition, and it costs only a very small sum.

Your signs should be clean-cut and conspicuous, but still dignified and in harmony with the general color-scheme of your store.

Window-displays are really one of the most important factors of publicity and one of the least expensive methods of obtaining the interest of the passer-by. Clean windows and attractive displays should be the continual duty of the wide-awake pharmacist; and right here let me emphasize the increased selling-efficiency of the window attractively decorated, bearing price tags on every item exhibited. It is fifty percent more effective by having the prices shown.

Within the store your show cases, your floors, your soda-fountain, your prescription-counter, all, should be continually considered as means of getting the confidence, respect and good-will of your customers.

A few dollar's worth of varnish and furniture polish, applied at regular intervals, adds greatly to the neatness of your store.

Perhaps in no business is cleanliness as important as in that of the drug store. The eternal dusting, scrubbing and cleaning of your store is one of the best investments in the publicity game.

Every container leaving your store, and particularly every prescription-container, should be of unquestionable neatness and cleanliness. The prescription-bottle only partly cleansed, with the label on crooked, showing paste on the edges, with a frail cork, and untidily wrapped, is not conducive to getting the good-will nor the confidence of your customers.

If that same prescription had been put into a crystal clear, clean bottle, properly filtered if necessary, with a neatly type-written label, put on straight, the bottle capped, then wrapped in white tissue paper and neatly tied, it would have added dignity to your profession and thereby increased the confidence and respect of your customers.

The use of embossed, neat, small stickers adds elegance to the appearance of your merchandise.

The neat appearance of your clerks, and the proper decorum in which they do their duties in front or in the rear of your store, also are important factors in the attainment of your customer's good-will.

Service: In this word "service" we have the real kernel of the secret of modern merchandising, and in this age the word "service," applied to the merchant, has taken on a new and a larger meaning than that of old, when service meant servility.

Service, as applied to modern merchandising, enters into every feature of your

business. You, as the retail merchant, are therefore serving the convenience of the public, and the more convenient your store becomes to the public, the larger your rewards will be in the commercial, as well as the ethical results.

The idea which I wish to *emphasize* to you, gentlemen, is that you should become an absolute need to the community in which your store is located. Then, and then only, you can be classed among the successful druggists.

The telephone is a factor in obtaining this service-good-will. The boundaries of your store extend just as far as the farthest telephone owner who is located within convenient and profitable delivery-distance from you.

Make those of your neighbors who have telephones, get the habit of thinking your telephone number when they are in need of drug-store goods. If you accomplish this, and give them quick and cheerful service, you will surely increase your business.

The above methods we will call "Passive Advertising," to differentiate them from the constantly changing and the planning of the "Active Advertising" methods.

Throughout this country there are thousands of concerns making a specialty of planning and executing "Active Advertising" methods for the business world.

Many of these are splendid concerns, doing wonderful and profitable work for their clients, but many, through want of knowledge and experience, are costing the business world millions of dollars in luxurious and extravagant methods of publicity. And, as a whole, it is not feasible for the retail merchant to employ this class of help; first, due to the expense, and next, to the danger of putting your advertising service in hands which will merely make it a burden to you.

Now, if the retail merchant would give a thought to some of the recognized effective, but still inexpensive, methods of publicity and would understand how simple these methods are, he would surely give this part of the merchandizing-scheme more consideration than he now is doing, and thereby profit to a greater extent.

The question of a reasonable sum for the active advertising appropriation is the first one to be considered. For a retailer a sum equivalent to $2\frac{1}{2}$ percent of the total business done should be a fair annual appropriation for this purpose.

Now, how should a retail druggist expend this sum in such a manner that it would show a decided profit?

Under certain conditions, the local paper undoubtedly furnishes a very satisfactory and effective method to expend a part of this sum, but in larger cities and their suburbs, the carrying of an advertisement in that city's daily paper not alone involves the expenditure of a much greater sum, but in this case the cost of the ad. covers a section from which the retailer could not hope of getting any returns, due to the distance the prospect lives from the store, so the *pro rata* cost of the circulation of this paper in your locality makes it prohibitive.

Every package leaving your store, gives you the means of distributing advertising to people who are accustomed to come to your store. Therefore, circulars, such as you get up yourself, such as are gotten up for you by the manufacturers, and yearly calendars, should be enclosed with the purchase of every customer.

This cost is not very great and should be less than 10 per cent of your total active advertising appropriation.

An occasional large flyer, covering some event in your store, like that of opening a new department, or "featuring" the soda-water fountain, or calling attention to some specialty which you wish to dispose of quickly, can be made very effective but should be carefully planned and distributed.

Here the principal expense is the cost of reliable distributors. From \$2.00 to \$2.50 per thousand is the usual cost for getting such advertising matter distributed in a reliable manner. An estimate of about 20 percent of your appropriation should be charged against this method of publicity.

The custom of placing your advertisements in the programs of local fairs, dances, etc., should not be charged to advertising, as it is considered to be merely money thrown away from the publicity standpoint. It is undoubtedly a judicious thing to do at times, to retain the good-will or at least to insure yourself against the ill-will of the kind of people who call on you to solicit this "Hold-up-Money."

I suggest that this should be charged to "Profit and Loss." I can see no other place for this expenditure. It is a very thinly-veiled procedure for either charity or blackmail.

There has recently come into vogue another method of publicity, which is styled "Direct Mail Advertising," and it is this method which I to-day will strongly advocate for the retail druggist. It seems to hit "the nail right on the head," and a tremendous amount of evidence can be brought forth to show that it is the most profitable of all methods of getting more business, and I strongly advise that the balance of the "Active Advertising" appropriation should be expended on this feature.

"Direct Mail Advertising" means the sending through the mail of either post-cards, personal letters, pamphlets, blotters, or any other matter directed to some specific person at some specific address.

A profitable direct mail-advertising campaign depends, firstly, on the persons to whom you address this matter; secondly, on the matter itself; thirdly, on the proximity of the recipient of this to your store, either by means of personal visit, by telephone call, or by parcel-post delivery.

I will take up each point separately and in detail.

Your Mailing List: The mailing list should be carefully prepared and kept up to date, and should be divided in two sections: First, your "Present customers";—second, "Prospective customers."

The Present customer's list you can of course obtain from your ledgers, from personal information by your clerks and yourself, and by inquiry at the time of their visit, and should be used at regular intervals.

The Prospective customer's list should be carefully prepared and kept to date, and is the important part of a sound foundation of direct mail advertising, and requires constant inspection and revision.

It is evident that it would not pay you to try to reach a man who lives too far away from your store, unless he was on a direct mail-route and not more convenient to some other drug store.

The way I obtained our mailing-list was this. I took a map of the locality of our store, then I marked each street corner to which we could conveniently and inexpensively send a messenger-boy. This then, gave me our first zone of direct delivery.

I then procured a Roxbury Blue Book and the telephone book and by checking off the persons in the blue book who live within our zone of delivery, and who also were up-to-date enough and in such close touch with our store that they owned a telephone, I put on the mailing-list, and now we are reaching these families by direct mail at frequent intervals.

Club-membership lists, church-membership lists, voting-lists and rural free delivery-lists are all good means for getting your mailing-list from.

Keep your list in the form of a card-catalogue and, whenever a prospect becomes a customer, transfer her or his name to the customer's-list.

If the series runs out without a sale, transfer your card to the catalog of "Dead Ones."

Your mailing-list is one of your most valuable assets. It represents the present good-will of your business and future prosperity.

Each card should indicate the proper place of recording information, such as Full Name, Address, Send Statement To, Number in Family, Names of Other Members That Can be Used, Occupation, Advertising, Financial Rating, etc. You will thus be able to avoid sending a circular on razors and shaving material to Mrs. Brown, or some dainty toilet article to Mr. Jones, or advertising baby-requisites to a bachelor.

Salesmanship is a continuous and progressive study of human nature. Children grow up and forget their toys; men and women grow prosperous and their tastes change, but, if you can make each member of the family form the habit of thinking of your store when in need of drugs, you have made a valuable customer for years to come.

The matter which we are using at the present time, and find highly profitable, is that of personally addressed and signed type-written letters produced on the Multigraph. This splendid machine will turn out type-written letters easily and quickly, which cannot be told, apart, from personally dictated and type-written letters.

These letters I send out at frequent intervals direct to some member of each family. When I am talking candy, perfume and toilet articles, I address it to the lady of the house. When I am talking cigars or tobacco, I address the gentleman of the house.

I submit herewith copy of a letter on tooth brushes which we have used with excellent results:

Good Morning Mrs. Goodwin:

What a pleasure it is to use a good tooth brush! A well-shaped brush, one in which the bristles do not come out.

We have just secured six gross of the finest tooth brushes, manufactured by Deitsch Bros., the famous New York brush makers.

We wish to supply the discriminating families with a year's supply of these brushes, at especially low prices.

You can buy one or more of these brushes for 23c apiece, each in its own separate container.

These brushes are built to retail for 40c, others at 35c and 30c. We sell them all at one price: 23c, your own selection and assortment.

BUY A BOX OF SIX OR TWELVE.

We positively guarantee them to be the best constructed brush on the market, and will gladly risk all of our future business-relations on the quality of this brush.

In ordering just say, "Letter tooth-brush offer."

Respectfully yours,

LINUS D. DRURY CORP.

TEL. ROXBURY 48 AND GET DRURY'S INSTANT DRUG SERVICE.

These letters were printed on a high-class bond paper, correspondence size, and enclosed in similar high-grade envelopes. They were mailed at 4 o'clock in the afternoon, so that I would be sure that the lady of the house received it in the first delivery next morning, and probably would read it at the breakfast table.

You noticed that I advertised our telephone in the last line and promised them "Drury's Instant Drug Service" by merely saying "Roxbury 48" in the telephone. The result was that we received in the forenoon of the following day, nine telephone orders for tooth brushes, and all told, took forty-seven orders by telephone for this particular tooth-brush offer.

This, you must agree with me, is profitable advertising. I can cite you many other instances of similar results.

A few days before Easter, for instance, I sent out a letter about "Apollo" chocolates, and the direct result of this letter was an increase of fifty percent on our total candy business during the succeeding month.

The value of these letters did not end with the sale of the particular article we advertised, but they brought new customers, who now are buying other goods from us and will continue to do so as long as our service gives satisfaction.

How, then, brother pharmacists, can you say that you can never see direct results from advertising? It is a simple equation. A good mailing-list, pertinent advertising matter at the psychological moment, backed up by proper service gives — plus results.

This advertising by mail comes the nearest to expressing your own personality to the prospective customer in your own community, and, as one advertiser said, a well-written letter is equivalent to putting yourself in an envelope, sealing the flap, and letting "Uncle Sam" deliver you to your prospect's door.

Twenty-five dollars will reach five hundred people once a month, with this highly profitable method.

I believe that it is advisable to occasionally change the style of letters used, introducing novelties, and to enclose printed literature and I also advocate the occasional use of postal cards instead of letters.

This method should also be part of your physician's campaign. Personal letters to them describing your prescription-desk, or the especially fine galenical preparation of your own make, or the announcement to them of the stocking of some new and important product from the larger pharmaceutical houses.

Always enclose some pertinent advertising-matter with your statements.

Finally, I believe that all your "Active Advertising" should be so distinctively

YOURS that anybody should recognize it as "Your Advertising" by the merest glance, even without reading it.

Make yourself a necessity and a convenience to your neighbors; give them a "square deal" and good goods. Inform them of this every hour, with your "Passive" and "Active" Advertising, and if you do this, the department drug store need never be the "bug-a-boo" to your store, which it now threatens to become to many good pharmacists who hide their light under the bushel of obscurity.

A CRITICISM OF THE CHEMICAL TESTS FOR FRANGULA AND RHAMNUS PURSHIANA AS PROPOSED FOR THE NEW U. S. P.

E. N. GATHERCOAL, PH. G.

The introduction of chemical identity and quality tests in pharmacopœial crude-drug descriptions other than the alkaloidal assays, is a distinct advance in pharmacopœial pharmacognosy and should be encouraged.

Therefore in discussing the tests introduced into the text, descriptive of the anthraquinone drugs of the U. S. P., my object is to assist in the perfection of these tests.

The identity test for *Rhamnus Purshiana*, as stated in the Journal of the A. Ph. A., Vol. III, p. 398, is as follows: "Add 0.100 gm. of powdered *Cascara Sagrada* to 10 cc. of hot water, shake the mixture occasionally until cold, filter it and add sufficient water to make 10 cc. On the addition of 10 cc. of ammonia water to this liquid it should be colored an orange yellow."

Cascara responds very nicely to this test, though the color of the liquid after the addition of the ammonia water, is better described as a dark orange or even a light red-brown color. However, as no two people perceive a color exactly alike, I would not criticise the name of the color as stated in the text.

I would criticize however, the omission of a statement, after the test, as to from what other drugs this test is to especially distinguish *Cascara*. If in the application of the test, powdered *Rhubarb* is used, instead of powdered *Cascara*, the final color obtained is almost identical with that of *Cascara*.

The results of the above mentioned test, applied to a series of drugs, including other members of the anthraquinone group, is a matter of interest. The colors, against a white background with diffuse sunlight, of the liquid, after the addition of the ammonia, may be ranged as follows:

Cascara Class—Orange

Senna, Alexandria.

Senna, India.

Rhamnus Chlorophorus bark.

Rhamnus Californica bark.

Cascara, commercial.

Rumex.

Aloes.

Cascara, uncured, (kept but 3 months after collection).
Cascara, selected bark.
Cascara with 5% KOH solution, instead of ammonia water.
Rhubarb.

Frangula Class—Red.

Frangula, commercial.
Rhamnus Catharticus bark.
Frangula, selected bark.
Frangula, with 5% KOH solution, instead of ammonia water.
Rhamnus Crocea bark.

The solutions have been listed above in the order of their depth of color, the Alex. Senna being a decidedly light orange-yellow color; the commercial Cascara, a perceptibly deeper orange; the other three Cascaras, deeper yet, and the Rhubarb, forming the connecting link with the first Frangula. The Rhamnus Crocea bark is the darkest of all. The solutions almost form a finely graded series, from a light orange to a cherry red. All of the Cascara class are of the same color, differing only in intensity. Any one of the darker colors, suitably diluted with water, could be made to match any one of the lighter colors.

However, there is a distinction between the reds of the Frangula class and the oranges of the Cascara class, even when the red colors are diluted to the same depth of color as the orange colors.

If there should be placed, in parenthesis, after the description of the test, a statement indicating that this test is intended to distinguish Cascara from Frangula, all would be well, for the distinction in color obtained from Cascara, as compared with that from Frangula, is very pronounced: an orange from Cascara; a cherry red from Frangula.

The identity test proposed for Frangula, is similar to that proposed for Cascara, except that "a few drops" of ammonia are directed to be added, instead of 10 cc. of ammonia. I think the two tests should correspond in their wording. I found by comparing the whole series of drugs above enumerated, that the smaller amount of ammonia (0.3 cc.), answered practically as well as the larger amount (10 cc.).

The use of 1 cc. ammonia in the test for each drug would be fully satisfactory. The test should be followed with a statement that it is intended to distinguish Frangula from Cascara.

The quality test prescribed under each drug, works very satisfactorily. Used upon a number of different lots of Cascara and Frangula, the drugs in each case responded to the test, though with Cascara the final color was exceedingly faint. Here again, however, the distinction in the color obtained from Cascara and Frangula, was not as pronounced as the statement in the test would lead one to expect. In each case, the color of the ammonia, separated from the ether, is a red; more faint and more of an orange in the case of Cascara.

UNITED STATES PHARMACOPŒIA.

NINTH REVISION.

ABSTRACT OF PROPOSED CHANGES WITH NEW STANDARDS AND DESCRIPTIONS.

Copyright, 1914, by the Board of Trustees of the United States Pharmacopœial Convention.*

PART IV—FIRST PROOF.

A fourth installment of the Abstract of proposed new descriptions and standards and of changes in descriptions and standards is herewith submitted.

This Abstract embraces most of the proximate assays of crude drugs and galenical preparations.

Other Abstracts will be submitted later. Comments should be sent to the Chairman of the Revision Committee, Joseph P. Remington, Longport, Atlantic County, New Jersey, before August 1, 1914.

PROXIMATE ASSAYS.

GENERAL DIRECTIONS FOR ALKALOIDAL ASSAY.

Nearly all alkaloids are practically insoluble in water, but they are more or less soluble in alcohol, chloroform, ether, amyl alcohol, benzene, petroleum benzin, or mixtures of several of these. The salts of these alkaloids, however, are mostly soluble in water, but practically insoluble in most of the above mentioned solvents. The process of assay by immiscible solvents, which is generally known as the "shaking out" process, is based on this property of alkaloids, and it is carried out by treating the drug or a concentrated liquid extract with an immiscible solvent, in the presence of an excess of alkali, which liberates the alkaloid. The free alkaloid is dissolved by the immiscible solvent, which is then transferred to a separator and shaken with an excess of acid diluted with water. If the immiscible solvent is specifically heavier than water (e. g., chloroform or a mixture of more than one volume of chloroform to one volume of ether), it will separate in the bottom of the separator. It is then drawn off into another separator and shaken with a second portion of weak acid, and this operation is repeated until the alkaloid is all removed. If the immiscible solvent is specifically lighter than water (e. g., ether, or a mixture of more than two volumes of ether with one volume of chloroform), it will, on separation, form the upper liquid. The lower acid liquid is then drawn off and preserved, and the residual immiscible solvent shaken with successive portions of weak acid until wholly free from alkaloid. The volume and strength of the acid to be used is left to the discretion of the operator. It is best, however, to keep the total volume as small as possible. For the first extraction, it is advisable to use 10 Cc. of half-normal acid V. S., or sufficient to render the mixture distinctly acid; for the second extraction, use 5 Cc. of half-normal acid V. S. and 5 Cc. of distilled water. Repeat the extraction with the same proportion of acid and distilled water. In all assays, the extraction should be

*Permission to reprint for purposes of comment can be had on application to the Chairman of the Board of Trustees, J. H. Beal, Scio, Ohio.

continued until 0.5 Cc. of the acid washings shows only a very faint cloudiness on the addition of a drop of mercuric-potassium iodide T. S., or, in the case of caffeine and colchicine, on the addition of a drop of iodine T. S. The united acid solutions containing the alkaloid in the form of a salt are shaken thoroughly with ether and allowed to stand at least fifteen minutes for complete separation. The acid solution is then drawn off into a second separator, the ether washed with a little water and this wash-water added to the acid solution. The acid solution is then made alkaline in most cases with ammonia water, and shaken out with several successive portions of the appropriate immiscible solvent. The volume of the latter to be used in each operation is not less than half that of the acid solution, and the operation must be repeated as long as any alkaloid is extracted by the immiscible solvent. To test this, evaporate 1 Cc. of the last extraction and dissolve the residue in a few drops of diluted hydrochloric acid; the resulting solution should show not more than a very faint cloudiness on the addition of a drop of mercuric-potassium iodide T. S., or, in the case of caffeine and colchicine, on the addition of a drop of iodine T. S. The number of extractions required depends largely on the character of the alkaloid. With most alkaloids it is advisable to "shake out" three or four times before testing. Physostigmine and pilocarpine require about twice as many extractions as most other alkaloids. After having drawn off from a separator any liquid containing an alkaloid, a fresh portion of the solvent should be immediately added to the contents of the separator, and, before shaking, about 1 Cc. of this should be drawn off to wash out the stem of the separator. In the case of volatile solvents, the outside of the stem of the separator should also be washed by dipping it in the portion of the fresh solvent to be used for the next shaking out operation. Before evaporation the final ether or chloroform solution should be filtered through a dry filter, or preferably through a pledget of purified cotton. When filtering volatile solvents containing alkaloids through a paper filter, the upper edge of the filter should not reach the top of the funnel and the filter should be kept constantly full of the liquid until all has been added, then covered until the last of the liquid has passed through. Finally the filter should be washed thoroughly by applying a fresh portion of the volatile solvent to the top and carefully washing the outside of the funnel stem. Immiscible solvents heavier than water may be conveniently filtered by packing the stem of the separator below the stop-cock with absorbent cotton before drawing off the solvent. The alkaloidal solution is finally evaporated cautiously to expel the solvent, and the residue either dried to constant weight and weighed, or more commonly titrated with volumetric acid. When using aliquot parts, the solvent and the aliquot part should be measured at the same temperature. When pouring volatile liquids, the lower the temperature at which the operation can be conducted, the less the danger of loss by evaporation. The shaking or rotation of immiscible solvents should ordinarily be continued about one minute. Long or violent agitation should be avoided as permanent emulsions are apt to form. Should a partial emulsion form it may be removed by drawing off the clear portion, introducing a tuft of cotton and with a glass rod moving the cotton about in the emulsion next to the surface of the separator. Should the emulsion prove persistent, draw off the emulsified portion and evaporate the volatile solvent. The resulting residue, if alkaline, should be washed with each

successive portion of the solvent used in extracting the original solution. If acid it should be washed with acidulated water.

Another method of treating emulsions is to remove the emulsified portion to another separator, and wash it with successive portions of the solvent that is being used to extract the alkaloid. Emulsions are less apt to form in strongly acid or alkaline solutions than in those which are neutral or weak. Emulsification is sometimes prevented by increasing the volume of the aqueous or immiscible solvent. Chloroform or ether solutions of drugs rich in fat form very troublesome emulsions. In such cases it is advisable to add about 10 Cc. of normal sulphuric acid V. S., and evaporate off the volatile solvent, stirring with a rubber-tipped glass rod. When the resinous and fatty matter has been agglutinated, cool the acid solution and filter it through a small wetted filter into a separator. Re-dissolve the residue in 15 Cc. of ether, add 5 Cc. of tenth-normal acid V. S., evaporate off the ether as before, with continued stirring, and pour the acid solution through the filter into the separator. Repeat the extraction of the fatty residue with dilute acid two or three times and finally wash the filter free from alkaloids. Then make the solution in the separator alkaline, and "shake out" with immiscible solvents in the usual manner. The stems of separators, funnels and the lips of flasks, separators, and graduates, from which volatile solvents containing alkaloids have been poured or drawn off, should be carefully washed to remove any of the alkaloids left by evaporation. All alkaloidal residues to be determined volumetrically should be softened by the addition of about 1 Cc. of neutral alcohol or ether, the required amount of standard acid added, and the mixture gently warmed to insure the complete solution of the alkaloid. Finally add a sufficient quantity of distilled water to make the volume of the liquid for titration measure about 25 Cc. When the residue is to be weighed, if the final solvent has been chloroform, the last traces of that solvent should be removed by the addition of a little ether or alcohol followed by evaporation, care being taken to avoid loss by decrepitation, especially when evaporating a chloroformic solution of strychnine. This may usually be prevented by the addition of a little alcohol.

Aconitum.—No change in percent. of alkaloids required; "aconitine" changed to "ether-soluble alkaloids of Aconite." *Assay* as under Belladonna Root using 15 Gm. of Aconite in No. 40 powder and ether only as the immiscible solvent throughout the assay. Each Cc. of tenth-normal sulphuric acid V. S. consumed corresponds to 64.5 milligrammes of the ether-soluble alkaloids of Aconite.

Fluidextractum Aconiti.—The alkaloidal yield from 100 Cc. changed from "0.4 Gm. of aconitine" to "not less than 0.45 Gm. nor more than 0.55 Gm. of the ether-soluble alkaloids." *Assay*.—Drop from a pipette 15 Cc. of Fluidextract of Aconite evenly over the surface of 15 Gm. of purified sawdust (see p. 997) and evaporate to dryness at a temperature not exceeding 75° C. Then transfer the mixture to a 25 Cc. flask, and proceed as directed in the Assay of Belladonna Root, modifying the process there given by using the ammonia water with a little additional water to rinse out the dish in which the mixture was evaporated, and only ether as the immiscible solvent throughout the assay. Each Cc. of tenth-normal sulphuric acid V. S. consumed corresponds to 64.5 milligrammes of the ether-soluble alkaloids of Aconite.

Tinctura Aconiti.—The alkaloidal yield from 100 Cc. changed from "0.045 Gm. of aconitine" to "not less than 0.045 Gm. nor more than 0.055 Gm. of the ether-soluble alkaloids." *Assay.*—Evaporate 150 Cc. of Tincture of Aconite at a temperature not exceeding 75° C., until it measures about 20 Cc. Add 10 Gm. of purified sawdust to this liquid, incorporate it thoroughly and then continue the evaporation until the sawdust is dry. Transfer the impregnated sawdust to a 250 Cc. flask, and proceed as directed in the Assay of Belladonna Root, modifying the process there given by using the ammonia water with a little additional water to rinse out the dish in which the mixture was evaporated and only ether as the immiscible solvent throughout the assay.

Extractum Aconiti Pulveratum.—It yields not less than 1.8 percent. nor more than 2.2 percent. of the ether-soluble alkaloids. *Assay.*—Introduce 3 Gm. of Powdered Extract of Aconite into a 250 Cc. flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 Cc. of ether and 2 Cc. of ammonia water, shake the mixture vigorously every 10 minutes during a half hour, and when the drugs have settled decant 100 Cc. of the clear liquid, representing 2 Gm. of the extract. Proceed as in the Assay of Belladonna Root, modifying the process there given by using only ether throughout the assay.

Belladonna Folia.—No change in alkaloidal standard. *Assay* as under Belladonna Root using 15 Gm. of Belladonna Leaves, in No. 60 powder, increasing the amount of water added after maceration to 25 Cc. and, before titration, treat the final residue twice with 5 Cc. of ether, evaporating to dryness each time.

Tinctura Belladonnae Foliorum.—The alkaloidal yield from 100 Cc. changed from "0.03 Gm." to "not less than 0.027 Gm. nor more than 0.033 Gm. of the mydriatic alkaloids from Belladonna Leaves." *Assay.*—Evaporate 100 Cc. of Tincture of Belladonna Leaves on a water-bath until it measures about 10 Cc., transfer the evaporated liquid to a separator, and proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by increasing the ammonia water to 5 Cc., which, with about 5 Cc. of water, is to be used in divided portions to rinse out the dish in which the mixture was evaporated; before titrating treat the residue twice with 5 Cc. of ether, evaporating to dryness each time.

Extractum Belladonnae Foliorum.—The alkaloidal yield changed from "1.4 percent." to "not less than 1.18 percent. nor more than 1.32 percent. of the mydriatic alkaloids of Belladonna Leaves." *Assay.*—Dissolve 2 Gm. of Extract of Belladonna Leaves in 10 Cc. of diluted alcohol, transfer the solution to a separator and wash the vessel in which the extract was dissolved with about 10 Cc. of diluted alcohol in divided portions, adding the rinsings to the separator, and proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by treating the residue twice with 5 Cc. of ether before titrating, evaporating to dryness each time.

Extractum Belladonnae Foliorum Pulveratum.—It yields not less than 1.18 percent. nor more than 1.32 percent. of the mydriatic alkaloids of Belladonna Leaves. *Assay.*—Introduce 3 Gm. of Powdered Extract of Belladonna Leaves into a 250 Cc. flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 Cc. of a mixture of chloroform, 1 volume, and ether, 2 volumes, and 5 Cc. of

ammonia water. Shake the mixture vigorously every 10 minutes during a half hour and when the dregs have settled decant 100 Cc. of the clear liquid representing 2 Gm. of the extract. Proceed as directed in the Assay of Belladonna Root, modifying the process there given by treating the residue twice with ether, before titrating, evaporating to dryness each time.

Belladonnæ Radix.—No change in percent. of alkaloids. *Assay*.—Introduce 15 Gm. of Belladonna Root, in No. 60 powder, into a flask of about 300 Cc. capacity and add 150 Cc. of a mixture of chloroform, 1 volume, and ether, 2 volumes. Stopper the flask, shake it well and allow it to stand ten minutes, then add 5 Cc. of ammonia water and shake the flask vigorously every ten minutes during two hours. Now add 15 Cc. of distilled water, again shake the flask well, and, when the drug has settled, decant 100 Cc. of the solution, representing 10 Gm. of Belladonna Root. Filter the solution through a pledget of purified cotton into a separator, and rinse the graduate and cotton with a little ether. Completely extract the alkaloids from the chloroform-ether solution by shaking out repeatedly with weak sulphuric acid. Collect the acid washings in a separator, add ammonia water until the solution is decidedly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with chloroform. Evaporate the combined chloroform washings to dryness and dissolve the alkaloids from the residue in exactly 5 Cc. of tenth-normal sulphuric acid V. S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V. S., using cochineal T. S. as indicator. Each Cc. of tenth-normal sulphuric acid V. S. consumed, corresponds to 28.92 milligrammes of the mydriatic alkaloids from Belladonna Root.

Fluidextractum Belladonnæ Radicis.—The alkaloidal yield from 100 Cc. changed from "0.4 Gm." to "not less than 0.405 Gm. nor more than 0.495 Gm. of the mydriatic alkaloids from Belladonna Root." *Assay*.—Introduce 10 Cc. of Fluidextract of Belladonna Root into a separator and add 10 Cc. of water and 2 Cc. of ammonia water. Completely extract the alkaloids by shaking out repeatedly with chloroform and then extract the alkaloids from the chloroform solution by shaking out repeatedly with weak sulphuric acid until the alkaloid is completely removed. Collect the acid washings in a separator, add ammonia water until the solution is decidedly alkaline to litmus, and completely extract the alkaloid by shaking out repeatedly with chloroform. Evaporate the combined chloroform washings to dryness, dissolve the alkaloids from the residue in exactly 5 Cc. of tenth-normal sulphuric acid V. S. and then titrate the excess of acid with fiftieth-normal potassium hydroxide V. S., using cochineal T. S. as indicator. Each Cc. of tenth-normal sulphuric acid V. S. corresponds to 28.92 milligrammes of the mydriatic alkaloids from Belladonna Root.

Cantharis.—It should yield, when assayed by the process given below, not less than 0.6 percent. of cantharidin. *Assay*.—Introduce 15 Gm. of Cantharides, in No. 40 powder, into a stout bottle of not less than 250 Cc. capacity, add 150 Cc. of a mixture of benzene, two volumes, and purified petroleum benzin, one volume, and then add 2 Cc. of hydrochloric acid. Stopper the bottle tightly, shake it well, and allow it to stand over night. Now gradually warm the bottle and its contents to about 40° C. and maintain it at that temperature with fre-

quent shaking during three hours. Cool the mixture, decant or filter off 100 Cc. of clear solution and evaporate this rapidly in a tared beaker or wide-necked flask to a volume of about 5 Cc. Now add 5 Cc. of chloroform to the residue and set it aside in a moderately warm place. When the solvent has all evaporated, add to the crystals 10 Cc. of a mixture of equal volumes of absolute alcohol and purified petroleum benzin, which has previously been saturated with pure cantharidin, allow it to stand during fifteen minutes and then decant it through a pellet of purified cotton. Wash the crystals with successive portions of a saturated solution of cantharidin, similar to that directed above, until it is free from fat and coloring matter, and pass the washings through the same pellet of purified cotton. Then wash the cotton with a very small quantity of warm chloroform to dissolve any adhering crystals, collect the chloroform in the tared flask or beaker containing the washed crystals, evaporate off the solution with the aid of a blast of air, dry them at 60° C. for one-half hour and weigh. The resulting weight will be the amount of cantharidin obtained from ten grammes of Cantharides.

Cinchona.—The requirement that it “contain not less than 5 percent. of total anhydrous Cinchona alkaloids and at least 4 percent. of anhydrous ether-soluble alkaloids” changed to “not less than 6 percent. of the total alkaloids of Cinchona.” *Assay*.—Introduce five grammes of Cinchona, in No. 40 powder, into a flask of 500 Cc. capacity and add 200 Cc. of a mixture of chloroform, 1 volume, and ether, 2 volumes. Stopper the flask, shake it well, and let it stand ten minutes. Then add 5 Cc. of ammonia water, shake the flask frequently for one hour, and let it stand over night. Now add 10 Cc. of distilled water, shake the mixture vigorously and when the drug has settled, decant 160 Cc. of the solution, representing four grammes of Cinchona. Filter it through a pledget of purified cotton into a separator, and rinse both cylinder and cotton with ether. Completely extract the alkaloids from the chloroform-ether solution by shaking out repeatedly with weak sulphuric acid. Collect the acid solutions in a separator, add ammonia water until the solution is distinctly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with chloroform. Filter each portion of chloroform as it comes from the separator through a pledget of purified cotton into a tared flask, and wash the funnel and cotton with chloroform. Evaporate off the chloroform, add 5 Cc. of alcohol to the residue, and again evaporate. Repeat the evaporation with alcohol and dry the residue at 100° C. to constant weight. The weight will be the amount of total alkaloids from four grammes of Cinchona.

Fluidextractum Cinchonæ.—The alkaloidal yield from 100 Cc. changed from “4 Gm. of anhydrous ether-soluble alkaloids from Cinchona” to “not less than 4.5 Gm., nor more than 5.5 Gm. of the total alkaloids of Cinchona.” *Assay*.—Drop from a pipette 5 Cc. of Fluidextract of Cinchona evenly over the surface of 10 Gm. of purified sawdust and evaporate it to dryness at a temperature not exceeding 80° C. Then transfer the mixture to a 500 Cc. flask, and proceed as directed in the Assay of Cinchona, modifying the process there given by increasing the ammonia water to 10 Cc. Use this in divided portions to rinse the dish in which the mixture was evaporated and add the rinsings to the flask.

Tinctura Cinchonæ.—The alkaloidal yield from 100 Cc. changed from "0.75 Gm. of anhydrous ether-soluble alkaloïds" to "not less than 0.9 Gm. nor more than 1.1 Gm. of the total alkaloids of Cinchona." *Assay*.—Evaporate 25 Cc. of Tincture of Cinchona on a water-bath until it measures about 15 Cc., add 10 Gm. of purified sawdust, incorporate this thoroughly and then continue the evaporation at a temperature not exceeding 80° C. until it is dry. Transfer the impregnated sawdust to a 500 Cc. flask; proceed as directed in the Assay of Cinchona, modifying the process there given by increasing the ammonia water to 10 Cc. Use this in divided portions to rinse the dish in which the mixture was evaporated and add the rinsings to the flask.

Cinchona Rubra.—The requirement that it "contain not less than 5 percent. of cinchona alkaloids" changed to "not less than 6 percent. of the total alkaloids of Cinchona." *Assay* as under Cinchona, using 5 Gm. of Red Cinchona.

Tinctura Cinchonæ Composita.—One hundred cubic centimeters yields not less than 0.45 Gm. nor more than 0.55 Gm. of the total alkaloids of Cinchona. Proceed as directed in the Assay of Tinctura of Cinchona, modifying the process there given by using 50 Cc. of the Compound Tincture instead of 25 Cc. of the Tincture there directed. (Not assayed in U. S. P. VIII.)

Colchici Cormus.—No change in alkaloidal standard. *Assay* as under Colchicum Seed, using 15 Gm. of Colchicum Corm.

Extractum Colchici Cormi Pulveratum.—The alkaloidal yield changed from "1.4 percent." to "not less than 1.25 percent. nor more than 1.55 percent. of colchicine." *Assay*.—Proceed as directed in the Assay of Colchicum Seed, modifying the directions there given by using 6 Gm. of the Powdered Extract of Colchicum Corm instead of 15 Gm. of Colchicum Seed. The final weight will be the amount of colchicine from 2 Gm. of Powdered Extract of Colchicum Corm.

Colchici Semen.—No change in alkaloidal standard. *Assay*.—Introduce 15 Gm. of Colchicum Seed, in No. 60 powder, into a 500 Cc. flask, and add 300 Cc. of a mixture of 10 Cc. of solution of lead subacetate and 290 Cc. of distilled water. Weigh the flask and contents, and digest the mixture at from 60° to 70° C. for three hours, with occasional agitation. Cool, add distilled water to restore the original weight and filter off 200 Cc. Add 0.75 Gm. of sodium phosphate to the clear filtrate, shake the mixture frequently during half an hour, and filter off 100 Cc. representing 5 Gm. of Colchicum Seed. Shake out the alkaloïd from the filtrate with chloroform until completely extracted, as shown by testing with iodine T. S. in place of the usual mercuric potassium iodide T. S., and evaporate the chloroform solution, adding about 1 Cc. of alcohol and again evaporating. Repeat this operation once more and dry the residue to constant weight at 100° C. To this weighed residue contained in a flask add 5 Cc. of approximately tenth-normal sulphuric acid V. S. and 5 Cc. of distilled water and heat the mixture for ten minutes to 70° C. Now filter the liquid through a pledget of purified cotton, and wash the flask and cotton with distilled water, rejecting the filtrate and washings and removing as much of the water from the cotton as possible. Dissolve any insoluble residue that may remain on the cotton by washing it first with a little alcohol and then with ether; collect the alcohol-

ether washings in the flask, evaporate, and dry the residue to constant weight at 100° C. Deduct this weight from the weight of residue previously obtained. The difference will be the weight of colchicine obtained from 5 Gm. of Colchicum Seed.

Fluidextractum Colchici Seminis.—The alkaloidal yield from 100 Cc. changed from "0.04 Gm." to "not less than 0.036 Gm. nor more than 0.044 Gm. of colchicine." *Assay.*—Introduce 15 Cc. of Fluidextract of Colchicum Seed into a 500 Cc. flask, add 10 Cc. of solution of lead subacetate, previously diluted with 35 Cc. of water, shake the mixture thoroughly, then add 240 Cc. of water, again agitate the mixture and proceed as directed in the assay of Colchicum Seed.

Tinctura Colchici Seminis.—The alkaloidal yield from 100 Cc. changed from "0.004 Gm." to "not less than 0.036 Gm. nor more than 0.044 Gm. of colchicine." *Assay.*—Evaporate 150 Cc. of Tincture of Colchicum Seed on a water-bath to about 20 Cc., transfer it to a 50 Cc. graduated flask and rinse the evaporating dish with about 10 Cc. of water in divided portions. Then add 10 Cc. of solution of lead subacetate, shake the mixture thoroughly, add enough distilled water to make 50 Cc. and pour this into a 500 Cc. flask. Now add 250 Cc. of recently boiled distilled water, using part of the water to rinse the 50 Cc. flask and proceed as directed in the Assay of Colchicum Seed.

Guarana.—The requirement that it "contain not less than 3.5 percent. of its alkaloidal principles," changed to "not less than 4 percent. of caffeine." *Assay.*—Introduce 6 Gm. of Guarana, in No. 60 powder, into a flask and add 120 Cc. of chloroform and 6 Cc. of ammonia water. Stopper the flask, shake it frequently for half an hour, then let it stand four hours. Again shake the flask vigorously and when the drug has settled, filter the liquid rapidly through a pledget of purified cotton and collect 100 Cc. of the filtrate, representing 5 Gm. of Guarana. Evaporate the clear filtrate to dryness and dissolve the residue in weak sulphuric acid with the aid of heat. When the liquid has cooled, filter it into a separator and wash the container and filter with several small portions of distilled water. Now add ammonia water until the liquid is distinctly alkaline to litmus and shake out the alkaloid with chloroform until completely extracted, as shown by testing with idoine T. S. in place of the usual mercuric potassium iodide T. S. Evaporate the united chloroform solutions and dry the residue to constant weight at 100° C. The weight will be the amount of alkaloid from 5 Gm. of Guarana.

Fluidextractum Guaranae.—The alkaloidal yield from 100 Cc. changed from "3.5 Gm. of the alkaloids from Guarana" to "not less than 3.6 Gm. nor more than 4.4 Gm. of caffeine." *Assay.*—Introduce 5 Cc. of Fluidextract of Guarana into a separator, add 1 Cc. of ammonia water, and shake out the alkaloid with chloroform until completely extracted, as shown by testing with iodine T. S. Evaporate the combined chloroform solutions to dryness and dissolve the residue in 20 Cc. of distilled water with the aid of heat. Allow this to cool, filter it into a separator and wash the container and filter with several small portions of distilled water, adding the rinsings to the liquid in the separator. Then shake out the alkaloid with chloroform until completely extracted, as shown by testing with iodine T. S., evaporate the combined chloroform solutions and dry the

residue at 100° C. to constant weight. The weight will represent the alkaloid in 5 Cc. of Fluidextract of Guarana.

Hydrastis.—No change in percent. of alkaloids required, “hydrastine” changed to “ether-soluble alkaloids of Hydrastis.” *Assay* as under Belladonna Root, using 10 Gm. of Hydrastis, in No. 60 powder, and 100 Cc. of ether and taking 50 Cc. of the ether-solution, representing 5 Gm. of Hydrastis. Use only ether as the immiscible solvent throughout the assay and dry the residue to constant weight at 100° C. The weight will be the amount of ether-soluble alkaloids from 5 Gm. of Hydrastis.

Fluidextractum Hydrastis.—The alkaloidal yield from 100 Cc. changed from “2 Gm. of hydrastine” to “not less than 1.8 Gm. nor more than 2.2 Gm. of the ether-soluble alkaloids of Hydrastis.” *Assay*.—Proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by using 5 Cc. of Fluidextract of Hydrastis instead of 10 Cc. of the Fluidextract of Belladonna Root. Use only ether as the immiscible solvent throughout the assay and dry the residue at 100° C. to constant weight, instead of titrating it. The weight will represent the amount of ether-soluble alkaloids in 5 Cc. of the Fluidextract of Hydrastis.

Glyceritum Hydrastis.—100 Cc. yields not less than 1.12 Gm. nor more than 1.37 Gm. of the ether-soluble alkaloids of Hydrastis. (Not assayed in U. S. P. VIII.) Proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by using 5 Cc. of the Glycerite of Hydrastis instead of 10 Cc. of the Fluidextract of Belladonna Root. Use only ether as the immiscible solvent throughout the assay. Wash the final ether extractions with 10 Cc. of water, draw off the water and discard it. Then filter the ether solution through a pledget of purified cotton, wash the cotton with ether, evaporate the filtrate and washings, and dry the residue at 100° C. to constant weight instead of titrating it. The weight will represent the amount of ether-soluble alkaloids in 5 Cc. of the Glycerite of Hydrastis.

Tinctura Hydrastis.—The alkaloidal yield from 100 Cc. changed from “0.4 Gm. of hydrastine” to “not less than 0.36 Gm. nor more than 0.44 Gm. of the ether-soluble alkaloids of Hydrastis.” *Assay*.—Evaporate 50 Cc. of Tincture of Hydrastis on a water-bath until it measures about 10 Cc., transfer the evaporated liquid to a separator, and proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by using the ammonia water with about 5 Cc. of water, in divided portions, to rinse out the dish in which the mixture was evaporated. Use only ether as the immiscible solvent throughout the assay and dry the residue at 100° C. to constant weight, instead of titrating it. The weight will represent the amount of ether-soluble alkaloids in 50 Cc. of Tincture of Hydrastis.

Extractum Hydrastis Pulveratum.—It yields not less than 9.0 percent. nor more than 11.0 percent. of the ether-soluble alkaloids of Hydrastis. *Assay*.—Introduce 3 Gm. of Powdered Extract of Hydrastis into a 250 Cc. flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 Cc. of ether and 5 Cc. of ammonia water. Shake the mixture vigorously every 10 minutes during a half hour and when the dregs have settled decant 100 Cc. of the clear liquid,

representing 2 Gm. of the extract. Proceed as directed in the Assay of Belladonna Root, modifying the process there given by using only ether throughout the assay, and drying the residue to constant weight at 100° C. The weight will be the amount of ether-soluble alkaloids from 2 Gm. of Powdered Extract of Hydrastis.

Hyoscyamus.—The percent. of mydriatic alkaloids required, changed from "0.08" to "0.06." *Assay* as under Belladonna Root, using 30 Gm. of Hyoscyamus, in No. 60 powder, and 300 Cc. of the chloroform-ether mixture. Increase the amount of distilled water, added after maceration, to 40 Cc. and take 200 Cc. of the chloroform-ether solution, representing 20 Gm. of Hyoscyamus. Before titration treat the final residue twice with 5 Cc. of ether, evaporating to dryness each time.

Fluidextractum Hyoscyami.—The alkaloidal yield from 100 Cc. changed from "0.075 Gm." to "not less than 0.055 Gm. nor more than 0.075 Gm. of the mydriatic alkaloids of Hyoscyamus." Proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by using 25 Cc. of the Fluidextract of Hyoscyamus in place of 10 Cc. of Fluidextract of Belladonna Root; before titrating treat the residue twice with 5 Cc. of ether, evaporating to dryness each time.

Tinctura Hyoscyami.—The alkaloidal yield from 100 Cc. changed from "0.007 Gm." to "not less than 0.0055 Gm. and not more than 0.0075 Gm. of the mydriatic alkaloids of Hyoscyamus." *Assay*.—Evaporate 250 Cc. of Tincture of Hyoscyamus on a water-bath to about 10 Cc., transfer the evaporated liquid to a separator, and proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by increasing the ammonia water to 5 Cc., which, with 5 Cc. of water is to be used, in divided portions, to rinse the dish in which the Tincture was evaporated, before titrating treat the residue twice with 5 Cc. of ether, evaporating to dryness each time.

Extractum Hyoscyami.—The alkaloidal yield changed from "0.3 percent." to "not less than 0.215 percent. nor more than 0.288 percent. of the mydriatic alkaloids of Hyoscyamus." *Assay*.—Proceed as directed in the Assay of Belladonna Leaves, modifying the process there given by taking 5 Gm. of Extract of Hyoscyamus instead of 2 Gm. of Extract of Belladonna Leaves.

Ipecacuanha.—The percent. of Ipecac alkaloids required changed from "1.75" to "2." *Assay* as under Belladonna Root, using 10 Gm. of Ipecac, in No. 80 powder, and 100 Cc. of ether. Take 50 Cc. of the ether solution, representing 5 Gm. of Ipecac. Use ether only as the immiscible solvent throughout and dissolve the residue in 10 Cc. of tenth-normal sulphuric acid V. S. Each Cc. of tenth-normal sulphuric acid V. S. consumed corresponds to 24.0 milligrammes of Ipecac alkaloids.

Fluidextractum Ipecacuanhæ.—The alkaloidal yield from 100 Cc. changed from "1.5 Gm. of the alkaloids of Ipecac" to "not less than 1.8 Gm. nor more than 2.2 Gm. of the ether-soluble alkaloids of Ipecac." Drop from a pipette 10 Cc. of Fluidextract of Ipecac evenly over the surface of 10 Gm. of purified sawdust, and evaporate it to dryness at a temperature not exceeding 80° C. Then trans-

fer the impregnated sawdust to a 250 Cc. flask, and proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by increasing the ammonia water to 5 Cc. Use this with about 5 Cc. of water, in divided portions, to rinse the dish in which the mixture was evaporated, and add the rinsings to the flask. Now add 100 Cc. of ether, and take 50 Cc. of the ether solution, representing 5 Cc. of Fluidextract of Ipecac. Use only ether as the immiscible solvent and dissolve the residue in 10 Cc. of tenth-normal sulphuric acid V. S. Each Cc. of tenth-normal sulphuric acid V. S. consumed corresponds to 24 milligrammes of the ether-soluble alkaloids of Ipecac.

Jalap.—No change in total resin standard. The further requirement that "not more than 15 percent. of the total resin should be soluble in ether" is omitted. *Assay.*—Pack 10 Gm. of Jalap, in No. 60 powder, in a cylindrical percolator and extract it with alcohol until 100 Cc. of percolate is obtained. Transfer 20 Cc. of the percolate to a separator, add 20 Cc. of chloroform, mix the liquids, then add 20 Cc. of distilled water and shake the mixture thoroughly. When the liquids have completely separated, draw off the chloroform into a tared beaker, wash the contents of the separator with 5 Cc. of chloroform without shaking and draw it off into the beaker. Evaporate the chloroform solution on a water-bath, add about 2 Cc. of alcohol, again evaporate, then dry the residue to constant weight at 100° C. The weight will be the amount of total resin from 2 Gm. of Jalap.

Nux Vomica.—The requirement that it "contain not less than 1.25 percent. of strychnine" changed to "not less than 2.5 percent. of the total alkaloids of Nux Vomica." *Assay* as under Belladonna Root using 15 Gm. of Nux Vomica in No. 40 powder, and increasing the quantity of ammonia water from 5 to 10 Cc. and the time of maceration to 12 hours; also, for titration, dissolve the alkaloid in the residue in 10 Cc. of tenth-normal sulphuric acid V. S. instead of 5 Cc. Each Cc. of tenth-normal sulphuric acid V. S. consumed corresponds to 36.4 milligrammes of the total alkaloids of Nux Vomica.

Fluidextractum Nucis Vomicae.—The alkaloidal yield from 100 Cc. changed from "1 Gm. of strychnine" to "not less than 2.37 Gm. nor more than 2.63 Gm. of the total alkaloids of Nux Vomica." Proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by dissolving the alkaloidal residue in 10 Cc. of tenth-normal sulphuric acid V. S. instead of 5 Cc. Each Cc. of tenth-normal sulphuric acid V. S. consumed corresponds to 36.4 milligrammes of the total alkaloids of Nux Vomica.

Tinctura Nucis Vomicae.—The alkaloidal yield from 100 Cc. changed from "0.1 Gm. of strychnine" to "not less than 0.237 Gm. nor more than 0.263 Gm. of the total alkaloids of Nux Vomica." Evaporate 100 Cc. of Tincture of Nux Vomica on a water-bath until it measures about 10 Cc., transfer the evaporated liquid to a separator, and proceed as directed in the Assay of Fluidextract of Belladonna Root, modifying the process there given by using 5 Cc. of ammonia water with a little water, in divided portions, to rinse the dish in which the Tincture was evaporated and by dissolving the residue in 10 Cc. of tenth-normal sulphuric acid V. S. instead of 5 Cc.

Extractum Nucis Vomicae Pulveratum.—The alkaloidal yield changed from "5 percent. of strychnine" to "not less than 15.2 percent. nor more than 16.8 percent. of the total alkaloids of Nux Vomica." Introduce 3 Gm. of Powdered Extract of Nux Vomica into a 250 Cc. flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 Cc. of a mixture of ether, 2 volumes, and chloroform, 1 volume, and 5 Cc. of ammonia water. Shake the mixture vigorously every 10 minutes during half an hour and when the dregs have settled decant 100 Cc. of the clear liquid, representing 2 Gm. of the extract. Proceed as directed in the Assay of Belladonna Root, modifying the process there given by dissolving the alkaloidal residue in 10 Cc. of tenth-normal sulphuric acid V. S. instead of 5 Cc.

Physostigma.—No change in alkaloidal standard. *Assay.*—Introduce 15 Gm. of Physostigma in No. 60 powder, into a flask of about 300 Cc. capacity, and add 150 Cc. of ether. Stopper the flask, shake it well and allow it to stand ten minutes, then add 10 Cc. of an aqueous solution of sodium bicarbonate (1 in 20) and shake the mixture vigorously at intervals during four hours. Now add 15 Cc. of distilled water, again shake the flask well, and when the drug has settled, decant 100 Cc. of the solution, representing 10 Gm. of Physostigma. Filter the solution through a pledget of purified cotton into a beaker and rinse the graduate and cotton with ether. Add 20 Cc. of tenth-normal sulphuric acid V. S. and evaporate off the ether, stirring during the evaporation with a rubber-tipped glass rod. After the resinous and fatty matter has agglutinated, pour off the acid solution through a wetted filter into a separator. Redissolve the residue in the beaker in about 15 Cc. of ether, add 2 Cc. of tenth-normal sulphuric acid V. S., evaporate off the ether with continued stirring as before and pour the acid solution on the filter. Repeat this operation until all of the alkaloid is extracted and then wash the filter with distilled water until it is free from alkaloids. Collect the solution and washings in a separator, add sufficient sodium bicarbonate to make the solution decidedly alkaline to litmus and completely extract the alkaloids by shaking it out repeatedly with ether. Wash the combined ether with 10 Cc. of distilled water and filter the ether solution, washing the container and filter with ether. Evaporate the combined ether solutions to dryness, dissolve the alkaloids from the residue in exactly 5 Cc. of tenth-normal sulphuric acid V. S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V. S., using cochineal T. S. as indicator. Each Cc. of tenth-normal sulphuric acid V. S. consumed corresponds to 27.52 milligrammes of the alkaloids of Physostigma.

Tinctura Physostigmatis.—The alkaloidal yield from 100 Cc. changed from "0.014 Gm. of the ether-soluble alkaloids from Physostigma" to "not less than 0.013 Gm. nor more than 0.017 Gm. of the alkaloids of Physostigma." Evaporate 150 Cc. of Tincture of Physostigma on a water-bath until it measures about 20 Cc., add 10 Gm. of purified sawdust to the liquid and incorporate it thoroughly. Continue the evaporation on a water-bath, until the mixture is dry, then transfer the impregnated sawdust to a 250 Cc. flask, and proceed as directed in the Assay of Physostigma, modifying the process there given by using the solution of sodium bicarbonate, in divided portions, to rinse the evaporating dish:

Extractum Physostigmatis.—The alkaloidal yield changed from “2 percent. of ether-soluble alkaloids” to “not less than 1.7 percent. nor more than 2.3 percent. of the alkaloids of Physostigma.” Dissolve 2 Gm. of Extract of Physostigma in 10 Cc. of diluted alcohol, drop the solution evenly over the surface of 15 Gm. of purified sawdust, and rinse the vessel with 5 Cc. of diluted alcohol in divided portions, adding the rinsings to the sawdust. Evaporate the mixture to dryness on a water-bath, transfer it to a 250 Cc. flask, and proceed as directed in the Assay of Physostigma, modifying the process there given by using the solution of sodium bicarbonate in divided portions, to rinse the evaporating dish.

Pilocarpus.—Percent. of Pilocarpus alkaloids changed from “0.5” to “0.6 percent.” Assay as under Belladonna Root using 15 Gm. of Pilocarpus, in No. 60 powder, and decreasing the amount of water to be added after maceration to 5 Cc. Each Cc. of tenth-normal sulphuric acid V. S. corresponds to 20.8 milligrammes of the alkaloids of Pilocarpus.

Fluidextractum Pilocarpi.—The alkaloidal yield from 100 Cc. changed from “0.4” to “not less than 0.55 Gm. nor more than 0.65 Gm. of the alkaloids from Pilocarpus.” Drop from a pipette 15 Cc. of Fluidextract of Pilocarpus evenly over the surface of 15 Gm. of purified sawdust, and evaporate it to dryness on a water-bath. Then transfer the mixture to a 250 Cc. flask, and proceed as directed in the Assay of Belladonna Root, modifying the process there given by increasing the ammonia water to 5 Cc., which, with 5 Cc. of water is to be used, in divided portions, to rinse the dish in which the Fluidextract was evaporated. Each Cc. of tenth-normal sulphuric acid V. S. corresponds to 20.8 milligrammes of the alkaloids of Pilocarpus.

Stramonium.—No change in alkaloidal standard. Assay as under Belladonna Root, using 15 Gm. of Stramonium, in No. 50 powder, increase the amount of water to be added after maceration to 25 Cc., and, before titration, treat the final residue twice with 5 Cc. of ether, evaporating to dryness each time. Each Cc. of tenth-normal sulphuric acid V. S. consumed corresponds to 28.92 milligrammes of mydriatic alkaloids.

Tinctura Stramonii.—The alkaloidal yield from 100 Cc. changed from “0.025 Gm.” to “not less than 0.0225 Gm. nor more than 0.0275 Gm. of the mydriatic alkaloids from Stramonium.” Evaporate 100 Cc. of Tincture of Stramonium on a water-bath until it measures about 10 Cc., transfer the evaporated liquid to a separator, and proceed as directed in the assay of Fluidextract of Belladonna Root, modifying the process there given by using the ammonia water and about 5 Cc. of water in addition to rinse the dish in which the Tincture was evaporated, and treat the residue twice with 5 Cc. of ether, before titrating, evaporating to dryness each time.

Extractum Stramonii.—The alkaloidal yield changed from “1.0 percent.” to “not less than 0.9 percent. nor more than 1.1 percent. of the mydriatic alkaloids of Stramonium.” Proceed as directed under the Assay of Extract of Belladonna Leaves, using 2 Gm. of Extract of Stramonium.

Extractum Stramonii Pulveratum.—It yields not less than 0.9 percent. nor more than 1.1 percent. of the mydriatic alkaloids of Stramonium. Proceed as

directed under the Assay of Powdered Extract of Belladonna Leaves, using 3 Gm. of Powdered Extract of Stramonium.

Purified Sawdust.—(Insert among Reagents.) Moisten 1000 Gm. of Oak Sawdust, in No. 20 Powder, with water, pack in a cylindrical percolator and pour on enough of a 1 percent. sodium hydroxide solution to saturate the powder and leave a layer above it. When the liquid drops from the percolator, close the lower orifice and macerate the sawdust during 24 hours. Then proceed to percolate slowly until 5000 Cc. of the sodium hydroxide solution has been added, continue the percolation with 4000 Cc. of 1 percent. hydrochloric acid and then wash the sawdust with water until the acid is all removed, the percolate being neutral. Finally dry the powder.

TOTAL EXTRACTIVE AS A FACTOR IN FLUIDEXTRACT MANUFACTURE.

E. L. MAINES, PH. C., PHAR. D., AND R. J. GARDNER, PH. G.

The determination of total extractive is an important factor in the manufacture of fluidextracts, especially those of the non-alkaloidal drugs.

This principle is carried out in part by the assay methods for the oleoresinous drugs, such as *Aspidium*, *Cubeb*s, *Capsicum* and *Ginger*, and the resinous drugs, such as *Podophyllum* and *Jalap*. In these assays, however, the oleoresin and resin, respectively, are estimated, whereas, in the total extractive determination, all substances soluble in the percolating menstruum are determined combined.

The complete exhaustion of a drug is made more positive by total extractive estimations, provided of course, the proper menstruum is employed. It also gives an index to the possible yield in the manufacture of solid or powdered extracts.

Several conditions tend to regulate the amount of solids in a fluidextract, such as, nature of drugs, fineness of powder and menstruum employed. Such drugs as *Cincona* and *Ipecac* give varying amounts of extractive matter and indeed, in some instances, it is almost impossible to completely extract even their active principles.

In the alkaloidal drugs, however, the estimation of extractive matter is of little or no importance.

Drugs that are extremely difficult to exhaust are fortunately in the minority and in most cases complete extraction is readily accomplished and the total extractive yield fairly constant.

The manner of making total solid (extractive) determinations is so well known that it is not necessary to comment upon it in this article. A table of total extractive determinations is given below which represents estimations covering many years of work and the products of several of the largest manufacturers.

TABLE SHOWING TOTAL EXTRACTIVE OF FLUID EXTRACTS.

Fluid Extracts	Percent Extractive
Aletris	9-12

Remarks:—The term “Fluid” is applied to those preparations which do not represent the U. S. P. standard of strength.

MANUFACTURING LABORATORIES, BRISTOL-MYERS COMPANY, June 5, 1914.

.. PREPARATION AND ANALYSES OF VLEMINCK'S SOLUTION.*

JOSEPH L. MAYER.

A short time ago two samples of Vleminck's Solution were submitted to me with a request that, in view of the fact that the color of one sample was markedly different from the other, analyses be made to ascertain if they were properly prepared.

Since the National Formulary, only, contains a formula for the preparation, and various pharmaceutical authorities consulted, made no reference to a standard, it was necessary to make samples, to determine how the solution should be prepared and what should be the strength of the finished product. The following work was therefore undertaken.

Referring to page 81, 3rd edition of the National Formulary we found that “Liquor Calcis Sulphuratæ”—“Vleminck's Solution”—was directed to be prepared as follows:

Lime, freshly slaked	165 grammes
Sublimed Sulphur	250 grammes
Water, a sufficient quantity to make	1000 grammes

Mix the slaked lime with the sulphur, and add the mixture gradually to 1750 cc. of boiling water. Then boil the whole, under constant stirring, until it is reduced to 1000 grammes, strain, and having allowed the solution to become clear by standing in a well-stoppered bottle, decant the clear brown liquid, and keep it in completely filled and well-stoppered bottles.”

*Read before the Kings County Pharmaceutical Society, May 12, 1914.

We, accordingly, made up one-tenth of this formula, by taring a 600 cc. porcelain evaporating dish, adding 175 cc. of water, heating to boiling, and then slowly adding the mixture of freshly slaked lime and sulphur, constantly stirring while heating, until the weight was reduced to 100 grammes. The material was then decanted into a 4 oz. cork-stoppered bottle, allowed to stand until the next day, filtered and assayed for total sulphur by the following method:

"Measure 10 cc. of the clear sample in a 100 cc. measuring flask and fill to the mark. Analyze 10 cc. aliquots of this solution. Treat with 3 cc. of saturated solution potassium hydroxide or sodium hydroxide solution, following by 50 cc. hydrogen peroxide free from sulphates. Heat on the steam bath for one-half hour exactly, and then acidify with hydrochloric acid, precipitate with barium chloride,—in the usual way, in boiling solution,—and finally weigh as barium sulphate."

Multiplying the weight of barium sulphate by the proper factor gives the quantity of sulphur and this, multiplied by 100, gives the percentage.

Blanks were run on the reagents, and these determined the quantity of sulphate present, which was then deducted from that found in the actual analysis.

This is Avery's method, and it is suggested by the Association of official agricultural chemists for the analysis of lime-sulphur-dips and lime-sulphur-salt mixture (U. S. Dep't Agr. Bureau of Chemistry, Bul. 107 rev. page 34). It is an extremely accurate and simple test which in our hands yielded remarkably close results.

We also analyzed the sample for total sulphur in solution, mono-sulphur equivalent, thiosulphate sulphur, sulphate and sulphite sulphur, total sulphide-sulphur and total lime (CaO) in solution, following the method in the Bulletin of the Bureau of Chemistry, U. S. Department of Agriculture, No. 162, page 29, but seeing no advantage over the Avery method, we employed that in all our analyses and simply determined the total sulphur of which the above sample showed the presence of 10.838 grammes in 100 cc. of solution.

Another 100 gramme lot made up in the same manner contained 14.581 grammes of total sulphur in 100 cc. of solution.

This great variation in results, indicated difficulty in properly preparing the solution. We therefore referred to the directions in the N. F. and found it directed to add the lime and sulphur mixture "gradually to 1750 cc. of boiling water. Then boil the whole under constant stirring until it is reduced to 1000 grammes"; this procedure differs from mine in that it directs the water to be heated to boiling, the mixture of lime and sulphur added and the whole boiled under constant stirring until the weight is reduced to 1000 grammes.

Another 100 gramme lot was then made by strictly adhering to these directions and when assayed showed the presence of 4.448 grammes of total sulphur in 100 cc. solution.

My original reading of the process was, as above noted, to heat the water to boiling and then, while the water was still on the fire, to gradually add the lime and sulphur under constant stirring, and boiling until the proper weight was produced, whereas the last product was made by strictly following the N. F. by heating the water to boiling, taking it off the fire, stirring the lime and sulphur

in, putting it back on fire, stirring and heating until the proper weight was attained.

The above figures clearly indicated that the wording of the manipulation in the N. F. was faulty; therefore another batch of 100 grammes, employing the official quantities, was made by taring a 250 cc. Erlenmeyer flask, adding 175 cc. of water, heating on the hot plate until boiling, and then adding the lime and sulphur previously mixed and boiling on the hot plate, without stirring or further attention, until the weight was reduced to 100 grammes, transferred to a 4 oz. cork-stoppered bottle, allowed to stand until the next day, filtered and assayed.

The solution contained 29.162 grammes of total sulphur in 100 cc.

Another lot made by the same method contained 29.593 grammes of total sulphur in 100 cc. solution.

These figures indicate that, if the solution is prepared in a flask, the product will practically be of uniform strength.

It is true the N. F. does not state whether a flask or evaporating dish should be employed. The result of the failure to specifically state, that a flask or similar vessel be used, is shown, by the analyses, to yield preparations of indefinite strength. If a large flask is not at hand, vessels which are deep should be employed, the object being to avoid too rapid evaporation of water, as the proper preparation of the product requires several hours.

In view of the above results the Committee on National Formulary should revise the wording of the directions for the preparation of Vlemminck's solution, and thus insure a uniform product. If thought necessary a standard could be fixed for the preparation, and a method of assay appended.

I would take this opportunity to acknowledge my indebtedness to my assistant, J. H. Wiener, Ph. C., for assistance rendered in the preparation and analyses of some of the samples.

THE ASSAY OF MAGMA MAGNESIAE.*

CHARLES H. LA WALL, PH. M.

Magma Magnesiae is a form of medicinal whitewash employed as an antacid, consisting of a suspension of magnesium hydroxide in water. Its use has been popularized by a well-known proprietary preparation, and as every pharmaceutical manufacturer and many retail pharmacists are at present making their own product, the necessity for standardization for the production of uniformity becomes apparent, and the Committee on Scope of the Ninth Revision of the U. S. P., have wisely concluded to admit the preparation to the official list under the above title.

The proposed formula provides for a preparation containing about 5 percent of magnesium hydroxide in suspension in water, all appreciable amounts of other compounds being removed in the process of washing which the precipitate undergoes. From the standpoint of the pharmacist the simplest method of assay would

*Presented to the meeting of the New Jersey State Pharmaceutical Association, June, 1914.

be by evaporation to dryness, or evaporation and subsequent ignition, but experimentation has shown that the former method is inaccurate, on account of the varying states of hydration which the product assumes as it dries, and the latter method is no more accurate and is just as tedious as the more logical method of determining the alkalinity of the preparation by residual titration and then calculating the results to magnesium hydroxide. The following method was found to give very satisfactory results:—

Take, approximately, 3 gm. of the magma, in a tared 100 cc. beaker or dish. Weigh accurately and dissolve in 25 cc. of half-normal hydrochloric acid. Titrate the excess of acid with normal potassium hydroxide V. S., using phenolphthalein as indicator. The factor for magnesium hydroxide, with half-normal hydrochloric acid, is 0.0148.

An examination of twelve specimens by the foregoing method, showed the following results:—

		Percent of magnesium hydroxide

12.	Proprietary preparation.....	7.25

The foregoing results indicate the great need for standardization, in a product of which the variation, as shown in commercial samples, is such that there is a difference of over 300 percent between the strongest and the weakest.

If the present official process is adopted, it would seem advisable to establish a range, say from 4.5 to 5.5, which should be the extreme tolerance of variation in a product of this kind.

Sail on, O Ship of State!
 Sail on, O Union, strong and great!
 Humanity with all its fears
 With all the hopes of future years,
 Is hanging breathless on thy fate!
 —Longfellow.

COLLOIDS AND THEIR IMPORTANCE TO PHARMACY.*

CURT P. WIMMER, PHAR. D., NEW YORK.

If I remember correctly, it was about five or six years ago that my esteemed friend, Jerome Alexander, in conjunction with Professor Hallock of Columbia University, exhibited and explained the ultra-microscope for the first time at a meeting of the College of Pharmacy. A few months after that, at a meeting of the Chemist's Club, I had again occasion to view a number of substances in the ultra-microscope and, each time and ever since, have been greatly interested in the colloid state of matter and have made it my business to follow the rapid strides which this new science, called "Colloid-Chemistry," has made. The first sight of a substance in the colloidal state under the ultra-microscope is a truly impressive and remarkable one: the substance, which appears to be perfectly homogeneous and at rest when observed with the naked eye, is found to be full of life and motion. We see little particles oscillating back and forth; we see the everlasting, never-ending motion of matter. Again, a few weeks ago, I attended a series of colloid-chemical conferences held by Dr. Wolfgang Ostwald at Columbia University, and I felt that Colloid Chemistry is, and will be destined to be of the greatest importance to all sciences, but especially to pharmacy.

It is with a great deal of pleasure that I come before you to-night with the privilege of talking about colloids and their importance to pharmacy.

In the short space of an hour allotted to me, it will be possible only to skip over the surface of the science and to give the most important facts, omitting much that would be of great interest.

I have divided the subject matter of my lecture into two general parts:

1. The nature, preparation and properties of colloids.
2. Their importance to the sciences, especially to that of pharmacy.

The subject of colloids is a vast one, although the science, as such, is only about fifteen years old, and is growing at a pace which makes it well nigh impossible to keep track of it. Colloids have been prepared and used for centuries, but without any true conception of this state of matter.

Although true colloidal solutions have been prepared as far back as 1802 by Richter, in 1839 by Woehler, and again in the fifties by Faraday, Kuhn and St. Gilles, none of these investigators had an exact idea of the true state of colloidal sub-division, although some of them suspected that they had metals suspended in the liquid in fine subdivision. The first systematic investigations along these lines were made by Thos. Graham, an English scientist, in 1861 to 1864, who published his findings in "Philosophical Transactions," and in "Liebig's Annalen der Chemie." Graham studied dialysis—the diffusion of dissolved substances through parchment paper or a membrane. He observed that some substances passed readily into a surrounding pure solvent, while others did not or, at least, did so at an exceedingly slow rate.

*A lecture delivered before the New York Branch of the American Pharmaceutical Association, March 9, 1914.

Those which passed through, he found to be substances which could be readily obtained in crystalline form, those which did not pass through were usually amorphous or glue-like, so he divided all matter into two general classes: Crystalloids and Colloids (from colla, glue).

But Graham made another important discovery. He found that certain substances, which were said to be insoluble, could be obtained in so-called pseudo-solutions, (a term proposed by Franceschi di Selmi in the forties). Graham prepared solutions of Ferric Hydroxide, Chromium Hydroxide and others, and found that they did not dialyse, so he gave them the name "Colloidal Solutions," or "Sols," a term which is now accepted and used for a colloidal solution. It would lead too far to go into all of Graham's investigations; simply let me state that they laid the foundation for the colloid chemistry of to-day. After Graham, work on colloidal substances was done by others, but little importance was attached to it; the theoretical and practical researches of organic and inorganic chemistries dominated the scientific world. Whatever chemical change or phenomenon which could not be expressed by a formula was not considered worth investigation. Interest in the subject was re-awakened, however, in the late nineties, when Bredig succeeded in preparing colloidal solutions of heavy metals by the aid of the electric spark.

The actual impetus to the work on colloids, however, was given by the invention of the Ultra-Microscope by Zigmondy and Siedentopf in 1905.

Our present view of the nature of colloids is diametrically opposed to that of Graham. He distinguished two worlds,—the Crystalline and the Colloid worlds. Our present accepted view is, that there is only one world and that the colloid state can be assumed by any substance, solid or liquid, under appropriate conditions.

A general definition for a colloidal solution or a "sol" is this: A colloid is any solid, liquid or gaseous substance in a certain state of subdivision, or dispersion, in another solid, liquid or gaseous substance.

A substance which is subdivided or dispersed is called a "Dispersoid." In order to illustrate the above definition of colloid, I ask you to kindly look at Ostwald's Schema:

There are, of course, transition states between the above dispersions.

A colloidal solution, or "sol," consists of at least two substances, the dispersoid and the dispersion medium; a colloidal solution is, therefore, a "di-phasic heterogeneous system."

Inasmuch as solids, as well as liquids and gases, can form part of a colloidal system, we distinguish nine different cases, as follows:

<i>Dispersoid</i>	<i>Medium</i>
Solid	Solid——Ruby-glass, Sodium in Sodium Chloride, precious stones.
	Liquid——Suspension—Colloids. (See below.)
	Gas——Cigar and other smoke, cosmic dust.
Liquid	Solid——Water in salts, occluded water in crystals.
	Liquid——Emulsoids. (See below.)
	Gas——Vapors, Clouds—Foams.
Gas	Solid——Gases in lava.
	Liquid——Fog.
	Gas——Not a colloid system.

Of the above, the two systems, Solid-Liquid and Liquid-Liquid have been studied most thoroughly and are of special interest.

The following are the general characteristics of these two systems:

(a) *System*: Solid-liquid, also called "Suspension colloid."

Type: A gold-sol.

- (1) Viscosity is about that of the dispersion medium.
- (2) They are slightly turbid or opalescent. Under the ultra-microscope we see bright and distinct spheres.
- (3) They exhibit Brownian movement, the rapidity of which increases with increase of temperature and decrease of viscosity of dispersion medium.
- (4) They have a distinct electric charge. After addition of an electrolyte, they coagulate and separate. They become irreversible, viz., they cannot be brought in suspension again by simple means.
- (5) Centrifugation may separate them as fine powder.

(b) *System*: Liquid-liquid, also termed "Emulsion colloid."

Type is solution of albumen in water.

- (1) High viscosity (inner fraction). A tremendous increase of viscosity follows a slight concentration. Higher temperature decreases viscosity. For example, on heating a solution of gelatine from 21° C. to 31° C., the viscosity decreases by about 1000 percent.
- (2) They foam upon shaking.
- (3) They exhibit pseudo-fluorescence, (like suspensoids).
- (4) The Ultra-Microscope shows a bright field, particles or spheres are, as a rule, not seen.
- (5) They have no distinct electric charge.
- (6) They coagulate only upon addition of large amounts of electrolytes.
- (7) They may gelatinize or swell.

There are several different ways of classifying colloids, none of which has yet been definitely accepted.

Preparations of Colloids: Inasmuch as the colloids are in degree of dispersion, between coarse suspensions and molecular and ionic solutions, we have two general methods of preparation.

Coarse Suspension $\gg \longrightarrow$ Colloid $\longleftarrow \ll$ Molecular Sol.

- (1) Method of dispersion: We start with a solid or coarse suspension.
 - (a) Mechanical grinding—Colloidal osmium.
 - (b) Action of light—colloidal silver.
 - (c) Action of electric current—colloidal gold, etc.

- (2) Method of concentration: We start with one or more molecular solutions and obtain the colloid by chemical reaction. Colloidal silver, gold, barium sulphate, etc.

In using these methods, we obtain at times particles of different sizes; we remove the coarse ones by filtration and the molecular ones by dialysis.

Most metals have been obtained in colloidal solutions, either in water or in organic solvents, such as alcohol, pentane, ethyl-ether or iso-butyl alcohol. Even the radio-active elements, or their salts, have recently (see *Kolloid Zeitschrift*, Feb., 1914) been prepared in this condition.

The Properties of Colloids. (1) Mechanical properties. They exhibit Brownian movement when observed under the ultra-microscope. This is a dancing, trembling movement discovered by the English botanist Brown in 1827. The motion is back and forth from a fixed central point. Smaller particles move faster than large ones, particles larger than $3\text{--}5\mu$ in diameter do not show the motion any more. There are several theories for the cause of this motion; one is that the gravity of the particles is only partially overcome by the viscosity of the medium, that the particles fall or rise until the viscosity of the medium overcomes the gravity and the particles are pushed back again. In coarser suspensions, the gravity overcomes the viscosity and a separation takes place, viz., cream, in which the particles of butterfat are $2\text{--}10\mu$ in diameter.

(2) Diffusion: Colloids have been found to diffuse. They differ in this respect from crystalloids only in the rapidity of diffusion.

(3) Osmotic Pressure. The osmotic pressure of colloidal solutions is, as a rule, very slight; some have none at all.

(4) Gravity: The density of colloidal solutions cannot be calculated from the density of the dispersoid and that of the medium. Dispersoids show, as a rule, a volume contraction and the density increases with increasing dispersion. J. Rose determined the following figures for gold:

Gold, melted and pressed.....	19.33
Gold, by oxalic acid.....	19.49
Gold, by FeSO_4 —finest powder.....	19.55–20.71

(5) Optical properties: Most colloidal solutions appear to be clear and transparent when viewed with the naked eye. Often, a turbidity, fluorescence or opalescence can be noticed, especially in reflected light. A ray of strong light sent through a solution of this kind, will show the "Tyndall phenomenon," viz., the light is repeatedly reflected and polarized. The ultra-microscope is constructed so that all rays, except those reflected from the suspended particles, are excluded. We see the "halo," so to say, of the particles. The color of the colloidal solution varies with the degree of dispersion. System Liquid-liquid most often appears whitish to pale yellow. Gold "sols" may be violet, red, blue, green, orange. The intensity of the color is measured by the amount of white which must be added to get a certain tint.

(6) Electric Properties: The disperse-phase is charged either positively or negatively.

Positive charge have: Metal hydroxides, silicic acid and certain dyes like methylene blue.

Negative charge have: Metals and their sulfides, dyes like indigo, eosin, fuchsin, also starch, mastic and acacia.

Filter paper in water becomes negatively charged—a substance, therefore, which does not ascend the filter paper by capillarity, is positive in charge, viz., it coagulates on the paper.

The kind of charge is usually stated for water, for it may be different in other solvents; for example, it is the opposite charge from that in oil of turpentine. Graphite in oil is positive, in water it is negative. Addition of certain substances may reverse the electric charge; albumin becomes negative by addition of an alkali; it becomes positive on addition of an acid. In passing the electric current through a colloidal solution, the particles travel either to the anode or cathode, according to their charge. This is Electro-osmosis or Kataphoresis. Colloidal solutions conduct electricity considerably less than dissociated solutions. The addition of a so-called “protective colloid,” such as albumose, acacia, etc., imparts to the dispersoid the charge of the protective colloid. So, collargol, lysargin and other colloidal preparations carry the charge of the protective colloid used.

(7) *Jellification*: Under this head we distinguish (a) setting, and (b) swelling.

The setting or jellifying of colloidal solutions is due to changes in the internal dispersion and in hydration. Setting takes place upon warming and consequent concentration, or upon the addition of electrolytes. The amount of the latter must exceed certain minimal values and amounts, which differ greatly with the nature of colloid as well as electrolyte. Hydrophilous colloids increase their volume on being brought in contact with water—they swell. This swelling may go on to such an extent that the particles of the substance are torn apart and a colloidal solution results, or it may reach a certain limit and then stop. The setting and swelling of colloids is a very important phenomenon. Every substance or organ has a certain definite swelling-value, which may counter-balance or even overcome osmotic pressure. The force of swelling is often very great. Ostwald states that swelling peas lifted the cover of an iron pot which had been weighted down with 83.5 Kg. The swelling-pressure of starch has been found to be equal to a pressure of 2523 atmospheres. The old Egyptians drove wooden sticks into stones and poured water in them. The swelling of the wood broke the stones, which were used for building purposes. The curling of gelatine-films is due to a swelling, also the straightening or curling of hair in dry or moist air respectively. Interesting work has been done on the structure of jellies. When we dissolve a small amount of gelatine in a mixture of alcohol and water and allow to cool slowly, we note under the microscope, that small semi-liquid drops separate and, as their number increases, they adhere to one another and finally form a net-like structure. By varying the amount of the gelatine, we get slightly different results, but we find that jellies are sponge-like colloidal structures filled with colloidal solution.

Salts, or acids, or bases—in short, electrolytes, have great influence upon swelling.

Acids and alkalis increase swelling, as do many neutral salts. Gelatine swells more in the presence of Magnesium Citrate than in water alone. Calcium Chloride, Hydrochloric Acid and Sodium Hydroxide increase the swelling ca-

capacity very considerably. The cause for this must be sought in the chemical nature of these hydrophilous colloids. They are probably amphoteric, that is they have weak acid and alkali reaction at the same time. By an addition of acid or bases, they form more or less ionized salts, which in turn cause a hydration, or a taking up of water, with subsequent increase in volume. R. Chiari, in Vienna, found that he could distinguish between distilled water and ordinary water, by means of the degree of swelling of purified globulin, which he found to be very sensitive to electrolytes.

(8) Coagulation: When we boil a solution of albumin, or add Ammonium Sulphate, we coagulate the albumen. Coagulation is an electrical phenomenon conditioned by colloids of different electric charge or by electrolytes. The amount of electrolytes must, however, exceed certain minimum values.

Gold or platinum "hydrosols" can be coagulated by Ferric or Aluminum hydroxide "hydrosols," provided the amounts added are such as to exactly neutralize the electric charge of each other. A 1/10,000 percent solution of gelatine will coagulate a mastic emulsion; if more is added the gelatine will act as a protective colloid.

(9) Pectization is the gradual resolution of substances into the colloid condition; for example, when we treat silver or mercurous iodide with solutions of potassium iodide of different strengths, we will get a colloidal solution. Szillard, of Paris, has made a large number of interesting experiments in which he tried to prove that inorganic substances can act like albumens.

(10) Adsorption: We are all familiar with the property of charcoal to condense large volumes of gases, or to take coloring matter out of solutions; the various silicates, like fuller's earth, kaolin, etc., can be used for the same purpose. Gelatine and isinglass can also be used for clarification or decoloration. The analyst knows that the concentration of certain salts (viz., lead), is reduced upon filtration through paper. These phenomena are classed as adsorption phenomena and are due like many other properties of colloids to their tremendously large surface development. A cubic centimetre of a substance reduced to colloidal dispersion has a total surface of 600 square metres and the surface forces of the colloids are, therefore, very pronounced. Adsorption is caused by a decrease in the surface tension of the solvent conditioned by the dispersed substance, or a third substance added. Quincke showed that a substance which causes a decrease in surface tension of a colloidal solution, has a tendency to travel to the dispersoid phase and form a sort of covering around it.

Fats, fatty acids, albumen and its decomposition-products, decrease the surface tension of water very considerably and are also readily adsorbed. It appears that adsorption is a physical phenomenon and that no chemical process plays any part. Ostwald, to emphasize this, has termed it "Mechanical absorption."

(11) Reactions in jellies: When we allow chemical reactions to take place in jellies, we find that the reaction-product separates out in ring forms, which rings appear in periods. A gelatine "gel" containing potassium dichromate, with a solution of silver nitrate on top of it, will slowly show the yellow rings of silver chromate. Such rings are called "Liesegang rings" after the scientist who investigated them most thoroughly.

On reviewing what I have told you so far about the preparation and properties of colloids, I find that I have omitted much that is important and exceedingly interesting, but I must hurry. I hope, however, that another opportunity will present itself to take some one certain phase of colloid-chemistry and go into it more thoroughly. Time does not permit me to tell you anything about the methods of colloid research. Most of them are directed, of course, by the properties of colloids. Splendid and very promising results have been obtained by the method of ultra-filtration devised by Bechold. In fact, colloid chemistry has opened a field of research which is tremendously large.

There is no science in which colloid chemistry does not enter in some way or other, and as a system of knowledge it is of the utmost importance. Each of us here is a fine example of a heterogeneous polyphasic colloid system; so is the chair on which you sit, the nails which hold the pieces of wood together and the glue which lends stability. You arise in the morning—the linen of your bedding, the feathers of your pillows are colloids, you proceed to bathe and use soap—again a colloidal process. You have your breakfast which consists of colloids; digestion sets in—again a colloidal process; the cigar you smoke and the smoke you exhale are colloidal systems—and so on and on. To still more emphasize the importance of colloids, I beg leave to say a few words about their uses in the various arts and sciences.

Cookery and Foods: The kitchen is a great colloidal-chemical laboratory. Meat of young animals is richer in juice and of softer tissue than that of older animals. This depends upon the swelling value of the tissues, which value changes with the age. Meat, on boiling, loses 20-30 percent of its weight of water—no doubt a dehydration of a colloid. On frying meat, a heat coagulation prevents the loss of juice. Artificial foods are now classed according to their content of carbohydrates and nitrogen. The colloid chemist will classify them according to their swelling value, upon which depends primarily the degree to which a food can be readily absorbed. Milk will be examined as to its surface tension and viscosity, which show abnormal fat and protein contents. Addition of water is detected by coagulation with calcium chloride and the refractometer; the amount of milk sugar is estimated by the polariscope after removal of the milk colloids with colloidal ferric hydroxide. Cheese is albumen colloiddally dissolved in milk; the determination of the swelling-values of the different cheeses will, no doubt, solve the question of their digestibility. Bread and beer are colloidal preparations which are now being investigated. The taste of beer depends on its viscosity, due to colloids, and its electrolytes. The brewing water used, seems to have considerable influence upon the taste.

Mineralogy: Most precious stones owe their colors to minute quantities of a colloid substance, viz., in topaz?sapphire we have colloidal cobalt oxide, in ruby, chromium oxide. The opal is a "gel."

Metals: Steel is a system: Iron-Carbon-Iron Carbide. Tungsten filaments were made by pressing tungsten together with dextrin or syrup through small openings into wire form. The filament was then subjected to high heat to carbonize the organic material. Kuzel has improved this method by preparing a "tungsten-gel" by alternate action of acid and alkali upon finely powdered

tungsten. This is pressed into filaments and gives splendid results in the Tungsten lamp.

Dyeing and tanning are purely colloidal processes and our knowledge of these most important subjects has been considerably enriched by colloid chemistry.

The setting of cement is a colloidal process; pottery and porcelain ware are colloidal substances.

Photo-chemistry has made tremendous progress since Luppö-Cramer, of Dresden, has applied colloid chemical methods to its research.

Cellulose and its preparations are colloids: Parchment paper swells in presence of acid, mercerized silk in sodium hydroxide. A solution of cellulose in copper-ammonia solvent, is a colloidal solution. Rubber is a colloidal system. Vulcanization is an adsorption of sulphur by rubber.

To come nearer home: Enzyme-action is a colloidal process, so are the various immunity reactions, the Wassermann reaction, for example.

The urine, the blood, as well as all other body fluids are colloidal solutions.

Martin H. Fischer, of Cincinnati, has made very interesting experiments on the cause of oedema and finds that all swellings of parts of the body are due to abnormal acid production, which is again a colloidal phenomenon. He also finds that nephritis is caused by abnormal productions of lactic acid, which causes the kidney tissues to become soft and the appearance of albumen in the urine. The application of colloid-chemical methods has proved most fruitful in explaining the causes of many physiological phenomena, viz., muscle contraction, ossification, formation of gall-stones, disturbances of circulation, etc. Under the heading, "Importance of Colloids to Pharmacy," we must consider first of all the remedies which are colloidal and are supplied by the pharmacist. The first one of these was Ung. Cr   , which appeared in the market in 1896, and from then on, and especially in the last few years, colloidal remedies have been put forth, one after another, so that to-day we have a very large number of them, and with them has come a voluminous literature of their own. French physicians and pharmacists are especially prolific, and a French firm now puts on the market the following:

Electrargol	Colloidal silver stabilized
Electrauroil	" gold "
Electroplatinol	" platinum "
Electropalladiol	" palladium "
Electrocuprol	" copper "
Electroselenium	" selenium "
Electromartiol	" iron "

They are also investigating, at the present time, the physiological activities of

Electrotell��rol.....	Tellurium	Also, Thallium
" indiol.....	Indium	Cadmium
" uraniol.....	Uranium	Lead
" vanadiol....	Vanadium	Aluminum
" manganese..	Manganese	Oxides of heavy metals and
" cobalt.....	Cobalt	ferrocyanides, etc., all in
" nickel.....	Nickel	the colloidal state

The larger pharmaceutical manufacturers of England, Germany and the United States have also taken up the manufacture of such preparations. Names like

Collargol, Lysargin, Protargol, etc., are familiar to us. Collargol is prepared by reducing silver nitrite with ferrous citrate in the presence of dextrin, which acts as a stabilizer. Lysargin contains metallic silver protected by the sodium salt of lysalbinic acid. As to the action of these preparations, we may say in general that they have the same physiological activity as their salts would have in diluted solution, viz., colloidal silver is used as an antiseptic, colloidal iron is recommended for the different forms of anæmia. One of the prominent features of their activity is a certain catalytic action which they exert. Palladium colloid, for example, is now used for obesity. It seems to stimulate the oxidation processes of the body and it has been found that intravenous injection of this colloidal metal is followed by a considerable loss in weight. No bad side-effects whatsoever have been reported.

Considering next the time-honored remedies prepared by the pharmacist, I believe that I do not overstate matters when I say that fully 80 percent of all of our pharmaceutical preparations are colloidal. Our gums, resins, and many alkaloids will form colloidal solution by simply mixing with a solvent. We use gelatine, gum acacia, tragacanth, etc., to stabilize preparations. Emulsions, most liniments, our collodions are colloidal preparations. All of our fluidextracts, most of our tinctures and syrups, as well as glycerites, are colloidal preparations.

I will cite specific cases, which show that the pharmacist has made and is making daily use of colloid chemistry.

You prepare Peppermint Water by rubbing up the oil with purified talcum—you increase the surface of the oil so that it may be dissolved in the water—this is a colloidal solution—a colloidal-chemical process has been made use of. You make an emulsion by shaking up in a dry bottle some oil of turpentine with tragacanth and then add water and again shaking. This is colloid-chemistry—the system, oil-water, is stabilized by the tragacanth, which is adsorbed at the boundary lines of the two liquids and thereby forms a covering around the globule of oil. The stability of an emulsion is directly proportional to the dispersion of the oil. You prepare liniment of ammonia. The ammonium oleate formed, decreases the tension of the cotton seed oil toward the water and is, therefore, absorbed at the boundary line of the system, oil-water. You prepare vinegar of squills and boil it—the coagulation of the albumin is a colloidal process. We add alkalis to fluidextracts of senega and taraxacum, to prevent pepticization. We know that alcohol or salts in certain amounts, will crack emulsions; this is due to the dehydration of the colloid and subsequent coagulation. We distinguish between solution of ferric sulphate and Monsel's solution, by addition of sulphuric acid—this is a colloid-chemical test. Monsel's solution is a colloidal solution which is coagulated by the electrolyte H_2SO_4 .

Cold cream is a colloid-system water-fat. The water, the dispersed phase, is dissolved in the fat. We know that only such substances as are soluble in fat, are absorbed by the skin, and the principal action of cold cream depends upon its water contents.

Ferric hydroxide is used as arsenic-antidote because it adsorbes arsenous acid.

And so I could go on and on and recite to you manipulation after manipulation, test after test, used by pharmacists and belonging strictly to the field of colloid-chemistry.

What a field of research lies here before us! The scientific pharmacy of the future will be in a position to determine in advance what the action of certain remedies will be or, how certain remedies must be modified, to exert certain actions, or to make them more stable and presentable. Professor Thoms, of the University of Berlin, in a lecture delivered before the German Pharmaceutical Association, pleaded for more active participation of the pharmacists in researches of biologic standardization. Without wishing to detract one iota from his arguments, I want to call to your attention that in colloid-chemistry there is a field of research for the pharmacist which is not alone of interest and value, but also full of promise of reward.

The lecturer carried out the following experiments to illustrate his remarks:

Preparation of colloidal gold and of colloidal silver by the electric spark under water.

Preparation of colloidal gold and silver in different colors by chemical means.

The Tyndall phenomenon in gold "sols," in cigar smoke and other colloidal systems.

Different forms of dialysers—sausage—thimble—filters—parchment—colloidion, etc.

A number of Liesegang's rings and LeDuc's figures.

Preparation of coagulated colloidal Ferric Hydroxide.

Preparation of gelatinous Barium Sulphate, gelatinous charcoal, etc.

LIQUID PETROLEUM OR "RUSSIAN MINERAL OIL."*

Petroleum has been in use as a medicine from time immemorial. It was known to Herodotus 400 years before Christ and is mentioned by Plutarch, Dioscorides, Pliny and other early writers. It was extensively used by the Arabians and evidently played an important part in the practice of medicine in India, being known to the Bengalese as "Muthe Katel." The raw product was the substance used in earlier times and differed much in character and composition, as obtained from different sources.

As an internal remedy it was early employed in chronic pulmonary affections, in obstinate skin diseases, in rheumatism, and for the expelling of tapeworms. It was extensively used for these several purposes in France under the name "Oleum Gabianum" and in North America as "Seneka oil." The internal use of the refined product may be traced to a patent granted to Robert A. Chesebrough of New York, in June, 1872, for the manufacture of a "new and useful product from petroleum, named vaseline." This name was originally applied only to a semi-solid preparation, but later a liquid products known as liquid vaseline was marketed and for a time exploited as a cure for coughs, colds, consumption and a number of other diseases and conditions.

The liquid petrolatum has since become known under a variety of names, proprietary and otherwise, in addition to being used as a substitute or an adulter-

*From the Journal of the A. M. A., May 30, 1914.

ant for other, more costly, fats and oils. Some of the names applied to the product are:

Adepsine oil	Neutralol
Amilee	Olo
Atoleine	Paraffin Oil
Atolin	Paroline
Blandine	Petalol
Crysmalin	Petro
Deeline	Petrolax
Glyco	Petrolia
Glycoline	Petronol
Glymol	Petrosio
Heavy Petroleum Oil	Rock Oil
Liquid Albolene	Russian Liquid Petrolatum
Liquid Cosmoline	Russian Mineral Oil
Liquid Fossiline	Russian Paraffin Oil
Liquid Geoline	Russol
Liquid Paraffin	Saxol
Liquid Petrolatum	Terraline
Liquid Saxoline	Terralbolia
Liquid Vaseline	Usoleine
Mineral Glycerin	Waterwhite-Mineral Oil
Mineral Oil	White Paraffin Oil

A preparation similar to that official in the Pharmacopœia of the United States as liquid petrolatum has been included in many, if not all, of the foreign pharmacopœias, the official title under which this preparation is recognized being as follows:

Petrolatum liquidum, U. S. Pharmacopœia; Paraffinum liquidum, pharmacopœias of Great Britain, Germany, the Netherlands, Japan, Belgium, Austria, Denmark, Switzerland, Sweden, Seryia, Italy, Hungary and Russia; Oleum Paraffinæ, Spanish Pharmacopœia; Vaseline liquidum, French Pharmacopœia, and Oleum Vaselini (as a synonym) pharmacopœias of Denmark and Russia.

The requirements of the several pharmacopœias differ somewhat and the specific gravity as given is as follows:

U. S. P. VIII, 1905.....	0.870	to	0.940	at 25°
Ph. Brit. IV, 1895.....	0.885	to	0.890	at 15.5°
B. P. C. II, 1911, usually.....	0.875	or	lower	at 15°
Ph. Germ. V, 1910, at least.....	0.885			at 15°
Ph. Ross. VI, 1910.....	0.880	to	0.885	at 15°
Ph. Hung. III, 1909.....	0.88	to	0.89	at 15°
Ph. Ital. III, 1909.....	0.875	to	0.890	at 15°
Ph. Fr. V, 1908, about.....	0.875			at 15°
Ph. Serb. II, 1908, about.....	0.880			at 15°
Ph. Svec. IX, 1908.....	0.88	to	0.90	at 15°
Ph. Helv. IV, 1907.....	0.880	to	0.885	at 15°
Ph. Dan. VII, 1907, at least.....	0.880			at 15°
Ph. Austr. VIII, 1906, at least.....	0.880			at 15°
Ph. Belg. III, 1906, not below.....	0.880			at 15°
Ph. Japon. III, 1906.....	0.875	to	0.945	at 15°
Ph. Ndl. IV, 1905, not below.....	0.860			at 15°
Ph. Hisp. VII, 1905.....	0.840			at 15°

For pharmaceutical purposes, liquid petroleum may be divided into two grades, the lighter or more limpid oil, used extensively as a vehicle for oil sprays, and the heavier, more viscid oil generally recognized in European pharmacopœias and used as an ingredient of ointments and more recently as a remedy in the treatment of intestinal stasis.

Under petrolatum liquidum the U. S. P. recognizes a mixture of hydrocarbons, chiefly of the methane series, which occurs as a colorless or very slightly yellowish, oily, transparent liquid without odor or taste and having a specific gravity of about 0.870 to 0.940 at 25 C. For the U. S. P. IX, it is proposed to change this requirement somewhat so as to have it apply to a transparent liquid free from fluorescence, without odor or taste and having a specific gravity of from 0.845 to 0.940 at 25 C.

Such a requirement would include all of the available paraffin oils irrespective of origin. The now commonly available commercial liquid petrolatum, used for pharmaceutical purposes, is practically colorless and all of the better grade are free from odor or taste. The specific gravity varies from 0.855 to 0.895. The lighter oils, having a specific gravity of from 0.860 to 0.870, are usually preferred in the making of oil sprays or solutions of substances to be used as local applications. The product having a specific gravity above 0.875 evidently contains a considerable amount of dissolved solid paraffin which separates out at temperatures at or below 0 C., but readily dissolves again at temperatures above 10 C.

There is considerable difference in the chemical composition of the paraffin oils obtained from various sources. The American oil consists largely of hydrocarbons of the methane series, while the Russian oil contains naphthenes or hydrocarbons of the benzene series, having the empirical composition of ethylene (C_nH_{2n}) which may be considered as hydrogenated aromatic hydrocarbons, though they behave with reagents very much in the same way as do the hydrocarbons of the methane series.

Mineral oils with a naphthene base are best suited for making white petrolatum, and at the present time the production of the colorless water-white liquid petrolatum appears to be confined largely or almost exclusively to the crude product of the Baku district of Russia, though it is asserted that it is now also made from the Hanover (Germany) crude oil and that some is being produced by "cracking" the white solid paraffin.

It is also said that the American oil can be made water-white but that it is not being so produced at present for economic reasons; the yellowish oil, free from fluorescence, having a very wide sale, both as a lubricant and as a substitute for lard oil and other of the more costly lubricating oils.

From a pharmaceutical point of view it would appear important to note the physical characteristics of the oil and to insist on absence of color, absence of odor and taste, absence of acid and of alkali and a specific gravity in harmony with the purposes for which the oil is to be used.

During the past year or two liquid petrolatum has attracted considerable attention as a remedy in the treatment of intestinal stasis or chronic constipation, the practice of using it having been developed largely through its recommendation by Sir W. Arbuthnot Lane and his associates. This use of liquid petrolatum and of petrolatum products generally is by no means novel. N. A. Randolph,¹ of Philadelphia, was among the first to suggest its use for this purpose in an article published in 1885. Randolph also appears to have been the first to experiment with petrolatum and to determine its non-absorbability from the intestinal tract.

¹Randolph, N. A.: *Therap. Gaz.*, 1885, ix, 732.

In an article² in 1884 he concludes that "pure petrolatum while entirely unirritating to the digestive tract is valueless as a foodstuff."

The experiments recorded by Randolph were evidently prompted by the fact that vaseline and a number of imitation products then on the market were being sold as substitutes for lard and butter, and opinions regarding the food value of petroleum products appear to have differed very materially. Following the experiments of Randolph, Robert Hutchison in 1899 made a series of experiments to demonstrate that petroleum, petrolatum, paraffin and related products were absolutely unassailable by any of the digestive fluids, despite the "large vogue that had of late years been given to various petroleum emulsions, chiefly by ingenious and unterrified advertising." He came to practically the same conclusions arrived at by Randolph fifteen years earlier and pointed out that "liquid paraffin in one sense may be regarded as an artificial intestinal mucus and might in that way have some value on certain forms of constipation."

William Duffield Robinson³ reports on the use of a perfectly refined colorless and odorless petrolatum, supposedly of American origin. He was able to show that all of the product passed unchanged through the intestinal tract and could be regained from the feces. In his conclusions he expressed the belief that the effect of the administration of these petroleum products is far more than as a simple intestinal lubricant. In over fifty selected cases in which nutrition, digestion and body-weight were impaired, and the purest oil administered in 1- or 2-dram doses each day for a period of from four to six months, there was in every instance an improvement of weight, health and feeling of well-being. The administration of refined paraffin oil gave no discomfort in any instance, even in cases in which nearly a pint was given in a few hours.

William Ewart⁴ suggests liquid paraffin as a safe agent for the local treatment of the lesions in typhoid fever. He says in part: "Mineral oil, such as petrolatum or paraffin, is neither absorbed nor dissolved; therefore, after all absorbable ingestions are taken up by the lacteals, it will still remain in the bowel. In this way pure liquid paraffin is valuable, precisely because it is inert; moreover, it might some day, perhaps, be made the vehicle for effective topical remedies."

A. D. Schmidt⁵ quotes Stubenrath as having given liquid paraffin in the treatment of chronic constipation, and he himself gave as much as 20 gm. of liquid paraffin to adults without observing any injurious effect whatever. He says, "As a result of the administration of liquid paraffin, the feces are softened considerably and are found under the microscope to contain numerous minute globules of paraffin." He was, however, unable to recover from the feces the entire quantity of paraffin administered and believes that a certain portion of it, probably the fractions with a low boiling-point, are absorbed or possibly oxidized in the organism.

²Randolph, N. A.: *Proc. Acad. Nat. Sc., Philadelphia*, 1884, p. 281.

³Robinson, William Duffield: *Med. News*, 1900, lxxvii, 56.

⁴Ewart, William: *Brit. Med. Jour.*, 1902, ii, 1505.

⁵Schmidt, A. D.: *München. med. Wchnschr.*, 1905, lii, 1970.

Maurice Vejux Tyrode⁶ also refers to the use of liquid petroleum in the treatment of constipation.

Sir W. Arbuthnot Lane in his recommendations of liquid petrolatum calls it an ideal remedy for stasis, but cautions against the use of the lighter oil as extensively prescribed in this country as a vehicle for sprays in nose and throat work.

Paraffin oil is not absorbed from the alimentary tract and so far as known exerts no deleterious influence. It is usually given in quantities of from 10 to 20 cc. half an hour or an hour before meals or in larger doses, from 30 to 50 cc., at one time on retiring. From available evidence it appears that comparatively huge doses may be administered without the production of any untoward results. According to many observers, liquid paraffin should not be given with or after meals because of the inhibiting influence that it may have on the digestion of food. It is not soluble in water or the ordinary solvents and therefore cannot be diluted. The denser oils are preferably slightly warmed or drunk with warm water so as to obviate the disagreeable slimy sensation that persists when taken cold.

Volatile oils may be used in moderate amounts to give a distinctive taste to the otherwise rather insipidly tasteless paraffin oil. Among the more desirable oils to be used for this purpose would be oil of peppermint, oil of cinnamon, oil of betula or methyl salicylate and oil of cloves. From 2 to 10 drops of any of these oils can be added to a pint of the oil. When larger doses of the oil are to be given at one time, it would, of course, be advisable to use a comparatively smaller quantity of the volatile oil as a flavor.⁷

From the foregoing it would appear that apart from the Pharmacopœia of the United States, practically all other known pharmacopœias describe a water-white mineral oil under the title "Paraffinum Liquidum" or "Liquid Paraffin" as a colorless, odorless, tasteless, non-fluorescent, oily liquid, free from acids, alkalies and organic impurities. As explained before, the specific gravity of the preparation as recognized in other countries and as offered on the American market at the present time varies considerably, and there appears to be some difference of opinion as to the exact nature of the product that is preferable for use for different purposes. This matter requires further investigation.

Since the definition of liquid petrolatum in the U. S. Pharmacopœia permits the use of fluorescent products of widely varying specific gravities, it is recommended that physicians who desire the water-white non-fluorescent (Russian)

mineral oil should use the term "Petrolatum Liquidum, Grave," or "Paraffin Liquidum, B. P.," if the heavy product recommended by Lane is desired, and "Petrolatum Liquidum, Leve" if the light varieties are required. It is further recommended that under the foregoing names, manufacturers and pharmacists be requested to dispense the products, in accordance with the following descriptions:

Petrolatum Liquidum, Grave.—Heavy (Russian) Liquid Petrolatum.—Paraffinum Liquidum, B. P., liquid paraffin.—A transparent, colorless, tasteless, non-fluorescent, oily liquid, odorless when cold but giving off a faint petroleum odor on heating. This preparation should correspond to the requirements of the British Pharmacopœia for liquid paraffin and have a specific gravity of about 0.885 to 0.890 at 15 C. It is insoluble in water or alcohol, but soluble in boiling absolute alcohol and readily soluble in ether, chloroform, carbon disulphide, petroleum benzin, benzene and fixed and volatile oils. It serves as a solvent for volatile oils and related substances like camphor, menthol and thymol.

This is the type of preparation used by Sir W. Arbuthnot Lane, and his associates for internal administration. It is also used as a basis for ointments and salves and as a local application to wounds, ulcers and in certain forms of skin diseases in which a simple protective is desired.

Petrolatum Liquidum, Leve.—Light (Russian)—Liquid Petrolatum.—A transparent, colorless, tasteless, non-fluorescent, oily liquid, odorless when cold, but giving off a faint petroleum odor on heating. In other respects this preparation should correspond to the pharmacopœial tests for liquid petrolatum and have a specific gravity of about 0.860 to 0.875, at 15 C. Like the heavy variety of liquid petrolatum, it is insoluble in water and alcohol, but soluble in boiling absolute alcohol and readily soluble in ether, chloroform, carbon disulphide, petroleum benzin, benzene and fixed and volatile oils. It serves as a solvent for volatile oils and related substances like camphor, menthol and thymol.

This is a type of preparation extensively used as a vehicle for the oily sprays in nose and throat work. It is also being used as one of the constituents in the now popular paraffin oil cold cream and has been used to some extent for internal administration in the treatment of chronic stasis. Being more limpid than the preparation preferred by Lane, it is more readily taken, though greater care must be exercised in securing a sample devoid of the lighter fractions of petroleum distillates.

The mystic chords of memory, stretching from every battle-field and patriot-grave to every living heart and hearth-stone all over this broad land, will yet swell the chorus of the Union, when again touched, as surely they will be by the better angels of our nature.—*Abraham Lincoln.*

CHEMICAL AND PHARMACAL ARTS IN THE PALACE OF LIBERAL ARTS AT THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION.

In so large a division of industries as those assembled under the caption "Chemicals, Drugs, Dyes, and Medicines," it is difficult to obtain figures that have a direct comparative value. There are so many articles of manufacture that even in showing, extent, or volume, there is necessarily much duplication of total amounts, the finished product in one class or group becoming the raw material of another. For purposes of classification the Thirteenth Census includes thirty classes under the group denominated "chemicals and allied products."

In considering the statistical analysis, to be shown immediately, of this great group it will at once become apparent how intimately they are associated with the daily life of the people. The very existence of some of the classes, as established parts of our commercial system, is important knowledge to the masses. And by the same token, to gather together a characteristic representation thereof, as will be done in the Liberal Arts Palace of the Exposition, must confer a lasting benefit upon the people. Science, it may be said, applied to manufacture, takes no backward step. Even the abandonment of a compound, for the use of a newer and better one, marks a step in development. And here one people teaches another by universal displays of these pseudo-arts. An exposition, especially one emphasizing modernity in processes, becomes a world's laboratory. Inventive science, everywhere, is stimulated to the production of a like compound, and, thus stimulated, often produces a better one. And the light spreads, until the whole earth is illuminated by the idea, and its use becomes the common property of all men. In this the Liberal Arts' displays takes place second to none.

The sale of drugs throughout the world illustrates the principle of mutual benefit in trade, which may be stated by paraphrasing the socialistic propaganda, "from each people according to ability, to each people according to need." Drug-houses have their buyers in all parts of world. In laboratories of the nations, lies advancement in almost every public utility. The dissemination of this knowledge, by means of national exhibits, at an universal exposition, becomes a state problem. Just to know where to buy the anti-toxins, which have been discovered and developed for use in the free clinics of civic institutions, is of immediate and never-ending benefit to the people. Even the new work in social science, depends upon investigations in these departments of physical science.

We introduce here as comprehensive of this group of industries the following figures: In all there are 9427 establishments engaged in manufacture. These employ 237,988 wage earners (average number) and turn out products valued at \$1,111,915,753. Of these establishments the drug trade is especially interested in the following: Chemicals, 349 establishments, product \$117,688,887; drug grinding, 25 establishments, product \$6,006,999; oil, castor, 4 establishments, product \$904,825; oil, cottonseed, and cake, 817 establishments, product \$147,-867,894; oil, essential, 68 establishments, product \$1,737,234; oil, linseed, 29 es-

tablishments, product \$36,738,694; oil, not elsewhere specified, 189 establishments, product \$30,865,122; patent medicines and compounds and druggists' preparations, 3,642 establishments, product \$141,941,602; petroleum, refining, 147 establishments, product \$256,997,659; soap, 421 establishments, product \$111,357,777; sulphuric, nitric, and mixed acids, 42 establishments, product \$9,884,057; turpentine and rosin, 1,585 establishments, product \$25,295,017; wood distillation, not including turpentine and rosin, 120 establishments, product \$9,736,998.

In the class "chemicals" are included "acids, except sulphuric, nitric, and mixed acids, and such as are made by establishments in the wood-distillation industry; sodas; potashes, alums, coal-tar products; cyanides, bleaching materials; chemical substances made by electrical processes; plastics; compressed or liquified gases; fine chemicals, and all chemicals not covered by other more specific classifications"; "wood distillation, etc." includes pyroligneous acid, wood alcohol, acetates, tar, and charcoal made by the destructive distillation of wood in closed vessels at a red heat"; tanning extracts and liquors, including chrome tanning solutions; and mordants, sizes, gums, and dextrins"; and continuing through the list, which we have not space to specify further.

In group 36, chemical and pharmacal arts, Liberal Arts Palace, there were originally twenty-four classes, but not all the products in the census classification are included therein, part of them appearing in the Palace of Manufactures, Agriculture, and Mines and Metallurgy. The revised classification in the Liberal Arts Palace, contains twenty-one classes, showing equipment, processes and products, as follows:

"Class 148. Laboratory apparatus and utensils; lamps, blowpipes, presses, drying ovens, filters, furnaces, ovens, etc., used in chemical laboratory work.

"Class 149. Apparatus and instruments for making industrial and commercial analyses.

"Class 150. Equipment and processes used in the chemical treatment of animal substances, with their products; super-phosphates, soaps, candles, glycerine.

"Class 151. Apparatus and processes for the production by electrolysis of hydrogen peroxide, chlorine, hypochlorites, chlorates, soda, bleaching materials, and various other chemicals. Also electro-thermal apparatus and processes for chemical manufacture not otherwise specified.

"Class 152. Equipment and processes used in the manufacture of vegetable essences.

"Class 154. By-products for pharmacal use, obtained from the treatment of mineral substances, such as petroleum and coal tar derivatives, etc.

"Class 155. Equipment and processes used in treating waste matter from factories (by chemical or electrical methods), with a view to permitting their return to water courses or to the atmosphere.

"Class 156. Equipment for charcoal-work and the production of its various derivatives; methylated spirits, acetone, acetic acid, tar, wood alcohol, pyroligneous acid. Products of charcoal burning.

"Class 157. Apparatus and processes for the compression and liquefaction of gas. Liquified gases.

"Class 158. Apparatus and processes for the manufacture of artificial textiles.

"Class 159. Appliances and processes used in the manufacture of pharmacal products. Raw materials of pharmacy; sera and other biological products, as

bacterins, vaccins, tuberculins, etc.; drugs of mineral, animal and vegetable origin; crude, powdered and compound; special appliances for collecting, cleaning, peeling, slicing, cutting and garbling crude drugs.

"Class 160. Disinfectants; standardization of disinfectants; manufacture of disinfectants; drug preservation; drug sterilization; ampouls, etc.

"Class 161. Acids, alkalies, salts and compounds of every kind. Chemical elements derived from their compounds and chemical compounds not otherwise classified.

"Class 162. Refined sulphur and derivatives from sulphur.

"Class 163. Equipment and processes used, and products obtained, in the manufacture of phosphorus and matches.

"Class 164. Drug adulteration; methods of adulteration; methods of detecting adulteration.

"Class 165. Various products of chemical industries; tanning materials, waxes, essential oils, glue and gelatine; perfumes, cosmetics, and extracts; various glazes, printing ink, blacking.

"Class 168. Alcohols modified for industrial purposes.

"Class 169. Equipment and appliances for producing calcium carbide and for the storage of acetylene gas.

"Class 170. Insecticides; fungicides; parasitocides and methods of manufacture and use.

A mere glance at this classification discloses the fact that the showing of all these products is especially designed to benefit the public good. Nowhere in the whole exposition will the "pure food" laws find greater exemplification. Nowhere will the interested individual be better able to relate the whole to his daily living. Municipal authorities will be able to study the methods of amelioration which constitute their abiding problem, by witnessing the direct application of manufacture to use and the relation which the product bears to the public health. Not only this, but the retail druggist will be able to inspect the equipment and processes used in the manufacture of many of the articles which find standard sale over his counters. All of these results insure to the manufacturer-exhibitor a profitable return for the expense and trouble of installing his exhibit. When the fact is added that visitors and dealers from all parts of the world will witness, study and analyze the display, and experts will relate same to foreign markets, the benefits from a commercial point of view are still more apparent.

The infinity of creation is revealed as much by the microscope as the telescope. Science is yet in its infancy. The constitution of matter is not yet fixed. The atom has been succeeded by the electron. Where the material ends and the spiritual begins is a subject of fascinating speculation and fraught (if discovery be possible) with mystic possibilities in the treatment of disease. The germ theory has revolutionized in the short period of twenty-five years the practice of medicine. The chemical engineer, he who studies, long and minutely, crystals and compounds; what, for want of a better name, may be called the affinities of molecules or the laws of attraction and repulsion in material substances, has become a public servant and benefactor. And it behooves the man whose business it is to dispense the result of these labors to the people to keep abreast of every advance. Toxins and anti-toxins are not only in the hands of physicians licensed by the state, but they are in the hands of the pharmacist who must also receive

the permission of the constituted authorities to carry on his business. And general public results are justifying these cautions thrown around the use of all these products, dangerous or salutary, as the case may be.

Indeed, the wonders of modern chemistry are never ending, and the "apothecary shop" of old, has been transformed into a public clinic, from which remedies and compounds are dispensed to the public, for a nominal cost, that have become indispensable, because so well-known and understood by the pharmacist as to become fixed in the public regard. So marvelous are many of the modern discoveries that the ancient alchemist, with his dreams, is no longer the derision of the scientist. The transmutation of metals, in the case of some rare ones recently discovered, has been actually accomplished. Radium is, perhaps, the world's greatest wonder of today. Not all is understood. Effects are produced through the scientific process, which defy analysis, while the result remains. And in the case of some of the well-known disinfectants, results justify a use, when science is unable to explain the transformation.

The public value of the exhibits in this section of the Palace of Liberal Arts, therefore, cannot be overestimated. Foreign governments should see to it that public laboratories make contributions to this highly important department of the coming universal exposition. And manufacturers, by exhibit of their latest products, may reach unlimited markets in remote lands that will justify the investment of largely augmented capital.

LOYALTY.

"First, then, by industry you must fulfil your vow to your country; but all industry and earnestness will be useless unless they are consecrated by your resolution to be, in all things, men of honour; not honour in the common sense only, but in the highest. Rest on the force of the two main words in the great verse, "*Integer vitae, scelerisque purus.*" You have vowed your life to England; give it to her wholly—a bright, stainless perfect life—a knightly life. Because you have to fight with machines, instead of lances, there may be a necessity for more ghastly danger, but there is none for less worthiness of character than in olden time. You may be true knights, though perhaps not *equites*; you may have to call yourselves 'cannonry' instead of 'chivalry,' but that is no reason you should not call yourselves "true men." So the first thing you have to see to, in becoming soldiers, is that you make yourselves wholly true. Courage is a mere matter of course among well-born youths; but neither truth or gentleness is a matter of course. You must bind them like shields about your neck; you must write them on the tables of your heart. Though it be not exacted of you, yet exact it of yourselves,—this vow of stainless truth."—*John Ruskin, at the Royal Military Academy, Woolwich.*

Education is a better safeguard to liberty than a standing army.—*Everett.*

Papers Presented to Local Branches

PREPARATIONS OF THE NEW U. S. P.*

L. A. BECKER.

The comments which follow are made with the understanding on the part of the writer, that the *text* in the Pharmacopœia should be *concise*, of *positive value* (not valueless or non-essential), and so worded as to exclude all opportunity for quibble or legal interpretation, wherever such an ideal is obtainable.

Following the preparations, in the order published in the April number of the *Journal*, my attention was directed to the requirements for "Aqua."

Using a dilution of Tr. Ferric Chloride with water, (representing Iron, 1-100,000), as test solution, and applying freshly prepared H₂S water, somewhat cloudy with Sulphur, no noticeable change in color or turbidity was shown in several hours; heavy metals should show darkening in 15 minutes, according to the text. This test was made to determine if Iron could be detected by this test, when present in small amounts. On adding Ammonia water, a dark coloration was produced immediately. This is a requirement of the present "U. S. P." heavy metals test.

In the next test for the limit of iron, the statement "no blue coloration should be produced immediately (iron)," needs modification. Since, the application of this test to a 1-100,000 iron solution,—which, by the way, develops a marked color on aging,—does not give a positive result, interpreting the text strictly. It takes about half a minute for a green coloration to show, which develops into a definitely blue coloration in about one minute. This certainly is not "immediately," as any lawyer required to defend this condition would contend, and probably with success.

Iron dilutions of 1-500,000, show a blue coloration in from three and one-half to five minutes; dilutions of 1-1,000,000, show this color in from seven-ten minutes. It is recommended that a definite time be stated, instead of the word "immediately," if this test is to be retained.

It would appear that these two tests establish a *much less rigid* standard, than the present "U. S. P." "heavy metals" test, if experimental contaminations serve, as well as those found in nature, as a guide to test them. Under Aqua Destillata, the present standard allows 7.5 Mg. per 100 cc. and not 5 Mg., as reported by the committee in comparison with the new standard of 1 Mg. Thus making the allowable residue, 7.5 times smaller, instead of 5 times, as the published text shows.

*Read before Chicago Branch, May, 1914.

Aqua Destillata Sterilisata: The requirement that only "freshly distilled water" may be used, and the recommendation that it be used "within 48 hours," surely makes its preparation difficult, and expensive for emergency use. One queries why those responsible for the restriction, "*freshly*," did not go the limit, and insist also on the, "all Jena glass" conditions, usually imposed by those claiming deleterious effects from products of less rigid manufacturing processes.

The medicated waters are all required to be made with recently boiled distilled water. Never having experienced any trouble with these preparations, I fail to see the reason for this, excepting the possibility that water, from which the air and CO₂ are removed, more readily takes up oils to saturation; or it may also be, that it is the purpose to sterilize the water just before using, to secure a better product. This latter, to insure success, requires bacteriological *technique* beyond the average pharmacist's attainment.

Liquor Sodii Chloridi Physiologicus: 8.5 gm. per litre, seems a rather large amount, especially when other salts are also added, to produce Ringer's or Locke's solutions. 7.5 gms.,—the mean between the extremes usually stated, namely, 0.6%-0.9% (from Howell's Physiology), may be less apt to produce hypertonicity than the higher amount. The hardship imposed by requiring freshly distilled water, holds also here and the recommendations regarding sterilization, I fear, will lead to many a dispute between Pharmacist and Physician should the former become the purveyor of this preparation to the latter.

For where there is infection,—where sterilized materials are employed, either instruments, dressings, suture materials, etc., or preparations,—the physician almost invariably seeks to put the blame on any other cause, however far-fetched his reasoning, rather than to ascribe bad results to his possible faulty *technique* or poor judgment. For the pharmacists' protection against accusations of this nature, the process of sterilization should produce unquestionable results, and the most thorough is none too safe. Therefore, I would recommend fractional sterilization—auto-claving from 15-20 minutes on three successive days at 115° to 120° C., or boiling for 1 hour on three successive days—allowing a shorter procedure only on the physician's explicit permission and by his direction. Also I would waive the requirement of freshly distilled water, proper keeping conditions being insisted upon for *Aqua Destillata*.

Liq. Sodii Arsenatis: The rubric states, "not less than 0.975%, nor more than 1.025%," but the assay requires "not less than 0.95%, nor more than 1.0%"; a discrepancy that ought to be corrected.

I cannot understand why Po. Ext. Cascara Sagrada should be directed to be made only three times the strength of the drug, when four times the strength is usually the requirement, for powdered extracts, and when most manufacturers make them of that strength. Surely pharmacists will not attempt manufacture of this extract when they are buying preparations more easily made.

The method of making Tr. Limonis Corticis and Tr. Aurantii Dulcis will probably meet with popular approval. The present "U. S. P." process for Tr. Nucis Vomicae certainly insures a more reliable preparation, with the skill required for its manufacture, than making the tincture from the drug, with assay by the pharmacist, will probably produce.

GENERAL CONSIDERATIONS.

The alcoholic preparations of the Pharmacopœia,—fluidextracts, tinctures, spirits, etc., should have the alcohol-content of the finished product stated definitely, and so adjusted that reasonably close adherence to the process would be followed.

There seems to be a tendency to complicate and increase the work in many formulas, without any apparent equivalent gain in the results obtained, for example: Liq. Calcis, Liq. Cresolis Co., Liq. Magnesii Citratis, Spt. Menth. Pip, etc.

In closing, I wish to state that the revision of the preparations—and this may also be found true of the other parts of the book—seem too much “library-made” and not enough “laboratory-made.” A thorough and practical revision could be made if the country’s most expert talent could be utilized, at times to suit the individual convenience, during the *interim* of the decennial conventions, as workers in laboratories especially arranged for this purpose, housed by the A. Ph. A. Such laboratories should be located in or near some centrally situated metropolis. In such laboratories tests and processes of great value to the profession, could be worked out, to meet conditions of environment similar to those surrounding the pharmacists of the different sections of the country.

PENNSYLVANIA STATE LAWS OTHER THAN PHARMACY LAWS
WHICH AFFECT THE RETAIL DRUGGIST.*

CHAS. H. LA WALL, PH. M.

The present era will probably be looked back upon by future historians as the “age of laws.” Many laws are now upon our national and state statute books, which class as crimes, acts which in a former generation were looked upon as simply evidences of sharp business practice. These offences, now punishable by law, have been aptly termed “artificial crimes,” because many of them are so technical in their character as to attach no moral disgrace to the individual found guilty of committing them.

The necessity for such laws has arisen on account of the complex relations brought about by our modern civilization, and in order to protect the honest, conscientious and upright individual from unjust and unfair competition on the part of those who are accustomed to look upon business from the standpoint of the old maxim “*Caveat emptor*,” and who do not realize that it has been superseded by the modern maxim “*Caveat vendor*.”

In many instances fraudulent practices have been developed to such a high degree of perfection, that the buyer is no longer able to act as a competent judge of what he is getting without the aid of expert advice. It is true in some cases these laws work an even greater hardship upon those whom they are designed to protect, than upon those whom they are calculated to punish, but that they

*Read before the Philadelphia Branch, May 5.

have become necessary, to a certain degree, at least, no one will deny, and their elimination will likely be brought about, only by the education of the individual to a point, where universal compliance with the underlying principles will voluntarily exist, through a proper understanding of the necessities of the situation.

All of these laws are mandatory in the highest degree. Wilful violation or guilty knowledge are not necessary to be proven in order to convict an offender. A proof of the violation carries with it a conviction, however innocently the violation may have occurred. The pharmacist in this respect is like the "Jungle Dweller," whose code of laws has been so admirably outlined by Kipling in the poem which concludes thus:

"Now these are the laws of the jungle,
And many and mighty are they;
But the head and the hoof of the law,
And the haunch and the hump is—Obey."

Of the pharmacy laws themselves, I shall assume that the pharmacist has sufficient knowledge, although in this connection there still exist some evidences of carelessness or wilful disregard of requirements which call for correction. I refer here more particularly to the practice of using substances for official or medicinal purposes which are labeled "For technical use only." This over-worked phrase has been a haven of refuge for manufacturers and sellers of sub-standard products, and unfortunately it is too frequently taken to mean that the article is up to the official standard in all but some minor particular, and the warning is forgotten or disregarded. An example of this kind which has come under my observation recently is of powdered magnesium carbonate supplied on an order for "Powdered Magnesium Carbonate, U. S. P." The package received was marked "Magnesium Carbonate, for Technical Use," and examination showed it to contain so much calcium carbonate, as to practically unfit it for any but filtering purposes.

Another case of the same kind, seen a year or so ago, was of gelatin marked "For Technical Use," and containing an amount of arsenic prohibitory to its use in medicinal or food products.

There is one class of products handled by druggists, for which, at the present time, there are no laws to govern the quality. This is the class of toilet preparations, such as soaps, washes, perfumes, creams, etc., for which no remedial properties are claimed and which come therefore neither under the classification of foods or drugs.

Among the Pennsylvania laws which might affect pharmacists is the general food law which prohibits adulterations and misbranding of foods generally. Maraschino cherries, for instance, which are very frequently used at the soda fountain and which are sometimes sold in the original containers, often contain sulphur dioxide compounds, resulting from the preliminary bleaching to which the cherries are subjected before dyeing them the bright red color. The national law permits the presence of sulphur dioxide if properly declared. The Pennsylvania state law prohibits it under all circumstances, except in dried fruits and molasses where the amount is limited. Such food products, therefore (other

than dried fruits and molasses in which limited quantities of sulphur dioxide are permitted when plainly declared), as are labelled to the effect that they contain sulphur dioxide, are illegal for sale or use in Pennsylvania.

Under the general food act also, would be included cake colored yellow with coal tar color, in imitation of eggs, or orange, or lemon, as the case might be; cake being frequently served at the soda counters of some of the larger stores. Under the general food act, also, would come instances of adulteration of confectionery. Adulteration in this connection need not take the form of the addition of harmful substances. The sale, for chocolate candy, of a confection containing other fats, such as cocoanut fat, which is commonly used to keep the confectionery from softening in hot weather and to cheapen it as well, is a violation of this law which is frequently detected and punished.

The sale, for licorice candy, of a product containing a minimum of licorice or none at all, but flavored with aniseed and colored with carbon black, is another example of a frequent violation of the food law. That the manufacturers know this, is shown by the fact that such goods are never labeled nor billed as the pure article, and thus the guarantee is of no value to the seller. The minimum fine for violation of the food act is \$60 and costs.

The milk and cream act, is one also which the pharmacist might easily violate, as he uses milk as an ingredient of the numerous and popular egg drinks. Milk, to be legal in Pennsylvania, must be whole milk, unskimmed and without the addition of water or any other substance, and containing not less than 3.25 percent of butter fat and 12 percent of milk solids. The use of skimmed milk, where milk is called for, is a distinct violation of the law punishable by a minimum fine of \$25. Under this same act also comes cream, which to be legal must contain not less than 18 percent of butter fat.

When a customer asks for vanilla-cream soda-water, how often is cream used in its preparation? Yet the use of any other substance than full-strength cream, is a distinct violation of the law. The use of milk or of artificially thickened products or of evaporated milk under such circumstances is a violation in each instance, punishable with the infliction of the penalty mentioned above.

Another, and a separate act, prohibits the use of any preservatives or coloring matter whatsoever in milk or cream. The minimum penalty for this offense is \$50. Thus, milk which had been skimmed and then thickened and colored or preserved, would be a violation of two separate and distinct acts, each carrying a separate penalty.

The non-alcoholic drinks act, is the next one which particularly concerns the pharmacist. In this act (which covers soda-water and all other similar beverages, either served by the glass or in bottles), a large number of preservatives are prohibited by name. Benzoic acid and benzoates are not in this list of prohibited preservatives and are the only preservatives in common use not specifically mentioned. Coal-tar colors are not prohibited under this act.

The strict interpretation of this act requires all beverages which are artificially colored and flavored, and which are not sold under distinctive names, to be declared as to their character. Thus, orangeade or lemonade, if artificially colored, must be declared as such, to the consumer. How this can be done with an un-

labeled drink sold by the glass and not drawn from any special kind of a cooling urn, upon which the lettering can be placed, is a problem. The use of placards hung up prominently or a notice accompanying the printed or stenciled list of beverages, such as frequently used, would seem to be the most efficacious method of accomplishing the result.

The penalty for violating the non-alcoholic drink act is also a minimum fine of \$25, as under the milk and cream act.

The ice cream act is the next under which the pharmacist may be liable. Ice cream must not contain any preservatives, must be true to name and must contain not less than 8 percent of butter fat, except in fruit and nut flavors, where 6 percent is required. Artificial colors are not prohibited when not used to conceal inferiority. Eggs, gelatin or vegetable gums are permitted where not used in excessive amounts.

This act also carries a penalty of a minimum fine of \$25.

The fruit-syrup act is one which is frequently violated because of ignorance of its existence. The non-alcoholic drinks act already referred to, was passed in 1909. The only other act even indirectly concerned with this subject, was the previous act of 1905, called the fruit syrup act. This act, which is short and specific, prohibits the same preservatives as were later prohibited in the non-alcoholic drinks act and in addition to this, prohibits the use of any coal-tar colors whatever. The use of coal-tar colors in the drinks themselves, was not prohibited by the later act, which, however, did not include the repeal of the former; so there now exists the anomalous condition that if a fruit syrup containing coal-tar color is sold as such it is a violation of the law, whether the presence of coal-tar color is declared or not, while if the same syrup be made up into a beverage and dispensed, it is perfectly legal if the presence of the artificial coloration is declared.

The anti-cigarette law of the legislative session of 1912-13 is of such recent origin and has been so prominently brought before the trade that it is not necessary to do more than refer to it.

The foregoing are the laws other than pharmacy laws which affect the retail pharmacist, and from the examples cited it will be evident to those who are familiar with trade conditions, that the reason why pharmacists have largely escaped punishment for violation of these laws, is because the activities of the food inspectors are kept so busy in other directions that they rarely take samples from drug stores, and not because violations do not exist. The best way to avoid danger of prosecution under these laws is to pay the same strict attention to their requirements that is paid to the requirements of the pharmacy laws, and then there will be no cause for fear.

PATRIOTISM.

Patriotism is a blind and an irrational impulse unless it is founded upon a knowledge of the blessings we are called to secure and the privileges we propose to defend.—*Robert Hall*.

Necrology

JAMES J. OTTINGER.

James Jeremiah Ottinger, of Philadelphia, died of pneumonia on Tuesday, May 19, 1914, as the result of a cold contracted while taking a motor ride.

Mr. Ottinger was sixty-five years old and was a widely known pharmacist. He graduated from the Philadelphia College of Pharmacy in 1868, and became an assistant to O. S. Hubbel, who for many years had a store on Chestnut Street, west of Broad.

For a time he was employed in the City of New York, but returned to Philadelphia to open a store at Twentieth and Spruce Streets, where he continued in business until his demise.

Mr. Ottinger became a member of the American Pharmaceutical Association in 1876, and of the Pennsylvania Pharmaceutical Association in 1899. He was a member, also, of the Alumni Association of the Philadelphia College of Pharmacy, the Navy League of the United States, the Young Republicans, and of the Philadelphia Country Club.

He is survived by a widow and daughter.

The funeral services were held on May 23, 1914, at his home. The Rev. Edward Yates Hill, pastor of the First Presbyterian Church, officiated. Interment was in Ivy Hill Cemetery, Germantown.

The honorary pall-bearers were Colonel J. Granville Leach, Professor Joseph P. Remington, Howard B. French, Earl D. Putnam, Drs. Charles S. Turnbull, Alfred Hand, Jr., Edward P. Davis, D. D. Smith, S. McClintock Hamill, Francis P. Packard and I. Minnis Hayes.

J. W. E.

MARIE BLAHNIK.

Mrs. Marie Blahnik passed away on Wednesday, April 22, 1914, at her home, 1225 South Harding Avenue, Chicago. Mrs. Blahnik was born in Christov, Bohemia. Some forty years ago she came to America, and, while always remaining true to Bohemia and to Bohemians, she was a most loyal American citizen, dearly loving her adopted country and all the activity and progress for which it stands. She was one of the oldest druggists, in years of service, in the city of Chicago. When women pharmacists were almost unknown, Mrs. Blahnik was successfully conducting a store of her own on West Eighteenth Street, which remained under her control until her death, although for some years past she had not taken an active part in its management.

She was a modest, womanly woman, "true as steel," kind, ever ready and anxious to lend "a helping hand." She had many friends among both the Bohemians and the Americans. "Those who knew her best, loved her best," could be said most truly of Mrs. Blahnik.

She was a member of the Illinois Ph. A., the A. Ph. A., the C. R. D. A., and N. A. R. D., and the Chicago Chapter of the W. O. N. A. R. D., and for years was Honorary President of the W. Ph. A., many times entertaining in her own true, hospitable manner its members in her home.

Her death was sudden, though as serene and peaceful as she had made her life. Her loss will be keenly felt, not only in her own home and among her own people, but throughout the community and by a very large circle of friends.

C. E. S.

SIR JOSEPH WILSON SWAN.

At the ripe old age of eighty-six years, Sir Joseph Wilson Swan has passed into his long rest. In his boyish days he showed a strong leaning to science, and was accordingly apprenticed to learn the "art and mystery of the Apothecary," or "Chemist," as it is more commonly termed in England. He was one of the pioneers to whom we owe the present perfection of the incandescent electric light, working in connection with the Brush Electric Light Company along that line of effort. Swan's filaments for his lamps were made by injecting a jet of colloid into a coagulating medium. This method was used for many years in the manufacture of these lamps and the manufacture of these filaments is said to have suggested to a French inventor the idea of the manufacture of artificial silk. He made many improvements in photographic processes and it is to him that we owe the invention of rapid dry plates and many other improvements in that field.

His honorable and successful career should stimulate every young pharmacist to effort, with the desire to emulate his service to the world. Napoleon said, "Every soldier carries a marshal's baton in his knapsack." So every young man, taking up the study of Pharmacy, may become a leader of the race in any of the various professions to which the study of Pharmacy opens the way.

THOMAS LATHAM.

Proceedings of the Local Branches

"All papers presented to the Association and its branches shall become the property of the Association, with the understanding that they are not to be published in any other publication than those of the Association, except by consent of the Committee on Publication."—By-Laws, Chapter X, Art. III.

Reports of the meetings of the Local Branches should be mailed to the Acting Editor on the day following the meeting, if possible. Minutes should be *plainly* written, or typewritten, with wide spaces between the lines. Care should be taken to give proper names correctly, and manuscript should be signed by the reporter.

<>

SAN FRANCISCO.

The Branch Association met on Tuesday evening, June 9th. The minutes of the May meeting were read and approved. Dr. H. M. Simmons was elected to membership.

After the dispatch of the routine business, Dr. Schneider called the attention of the members to the article on the anti-dysenteric properties of Chaparro Amargosa, by Dr. P. I. Nixon, which recently appeared in the Journal of the American Medical Association. Specimens of the plant were shown.

Dr. John Zieg presented a paper on "Some points for the pharmacist regarding the products used in organ-therapy." The doctor confined his remarks to those biological products which are derived from the adrenal, thyroid, thymus, pituitary and ovarian glands, which he stated have a therapeutic value quite well established.

The Branch adjourned to meet again on July 14th. On this evening Mr. J. Lengfeld will comment on some National Formulary preparations, Elixir of Ammonium Valerianate, Solution of Aluminum Acetate and Camphor-Menthol.

<>

SAINT LOUIS.

The Saint Louis Branch held its last regular meeting for the season in the Saint Louis College of Pharmacy, on Friday evening, May 15. In the absence of the president and vice-presidents, Mr. Ilhardt presided and introduced Mr. W. W. Ohlweiler, general manager of the Missouri Botanical Garden, who

gave an interesting talk on the subject, "Modern Herbal Garden."

Mr. Ohlweiler stated that there were growing at the garden between five hundred and six hundred medicinal plants divided into thirty-three groups, upon each of which its name was conspicuously displayed, and that the garden was kept particularly for the use of the pharmacists of the city and its vicinity.

He also outlined the course of school gardening which will begin this fall, in which an attempt will be made to teach the economic uses of plants from the standpoint of the botanist.

The following took part in the discussion which followed: Miss M. L. Sutter, Wm. K. Ilhardt, Dr. H. M. Whelpley, Prof. Francis Hemm, Julius C. Hoester, Prof. Leo Suppan, Chas. H. Bierman, Paul L. Goodale, Dr. Richard Kring, Gustav Kring, Carl T. Buehler, Franz Berg, Ferd Freeze and J. W. Mackelden.

On motion of Professor Hemm and seconded, a vote of thanks was extended to Mr. Ohlweiler for his discourse and the interest which he and the other members of the Missouri Botanical Garden are manifesting in our Association.

JULIUS C. HOESTER, Secretary.

<>

NORTHWESTERN BRANCH.

The April meeting of the Northwestern Branch of the American Pharmaceutical Association was held immediately after a special meeting of the Minnesota State Pharmaceutical Association at the Nicollet Hotel, Minneapolis, on April 15, 1914, at 8 p. m.

The following program was presented:—

1. Some Recent Problems of the Pharmacist—Mr. W. A. Frost.
2. Spices: Official and Unofficial Varieties—Mr. M. H. Haynes.
3. Some Tests on the Ethereal Tincture of Digitalis—Mr. F. A. U. Smith.
4. Should Students in Pharmacy take Military Drill?—Dean F. J. Wulling.

The meeting was preceded by a dinner at 6:30 o'clock.

The resignation of Chas. T. Heller as President was accepted with regret, and, upon nomination, A. D. Thompson, of Minneapolis, was unanimously elected to fill the vacancy. Mr. Truman Griffen was elected as Vice-President, the latter office having been made vacant by the promotion of Mr. Thompson.

Mr. Frost was the first speaker, and he confined his remarks chiefly to a consideration of samples of linseed oil that he had recently purchased, some of which were of such poor quality that it was impossible to make a soap from them. Mr. Frost stated that he was indebted to Mr. M. H. Haynes for the following analysis of one sample:

"The oil is probably manufactured by the so-called 'New Process,' which consists essentially of a carbon bisulphide or petroleum naphtha extraction and consequent recovery of the solvent by distillation. This process, seemingly, permits the extraction of considerable quantities of albuminous material, which, upon distillation of the solvent, is precipitated in the oil. In the case of this sample, the filtration process evidently was not perfect, for in addition to the albuminous matter, there is vegetable tissue present, which was demonstrated by diluting a sample of the oil with twenty parts of ether and centrifuging; the sediment thrown down being subsequently submitted to a microscopic examination. Alcoholic-saponification yields a value of 179, compared with the U. S. P. 187 to 195. The iodine absorption value is 151 in comparison with the U. S. P. of not less than 170. You will note that these results are low as compared with the U. S. P. figures. This, in my opinion, may be accounted for in a large degree in that the process of extraction removes the oil not only from the flax seeds, but also from all foreign seeds present which contain volatile and fixed oils. Commercial flax may contain up to 6 or 8 percent of foreign seed, and if such is present, the results above indicated may be anticipated, working by the new process. In the case of the old process of hot pressure, these foreign oils are not usually present. Will say that upon filtration, the sample in question yields a clean, normal-appearing oil, with the exception that the viscosity appears a little low."

Mr. F. A. U. Smith spoke upon "The Relative Value of Ether Extractive and Dilute Alcohol Extractive of Digitalis."

"In the PHARMACEUTICAL JOURNAL for February 7th, Thomas Stevenson referred to an article on Digitalis, by Louis Kolipinski, which appeared three weeks earlier in the Interstate Medical Journal.

Kolipinski concluded, from observed effects, that the regulated strength of the heart-muscle and the gastro-enteric irritation pro-

duced by digitalis, are the results of different principles, and that the principle which acts best on the heart is the least poisonous.

In the leaf of foxglove there is present an acid resin. This resin has always been regarded as inert.

Kolipinski proposes to name this resin, "Digitalic Acid." He regards it as the mother source of the various principles found in digitalis, and states that it is the least poisonous of digitalis-constituents and the best in its effect on the heart.

The purest form of "Digitalic Acid" is obtained by digesting the dried leaf with ether, although Kolipinski states that, for medicinal use, a sufficiently pure product may be obtained by digesting the dried leaf with sodium hydroxide and subsequently neutralizing with sulphuric acid. The product, "sodium digitalate," occurs as deep-green, non-crystalline lamellæ of considerable lustre, soluble in water, with formation of a greenish-blue solution. When prepared from the precipitated resin, it occurs as a brownish-colored powder, which forms a greenish-brown solution with water.

Kolipinski states, that experiments upon guinea pigs showed that, in large doses, sodium digitalate arrests the left ventricle in bloodless systole. Chemical results, he states, show that it gives uniformly all the good results of digitalis, without its toxic effects, and that it can be given hypodermically, without producing local inflammation or irritation. He recommends a single daily injection of 1/33 grain (0.0022 gm.). In urgent cases, the dose may be repeated later in the day, until the severity of the symptoms is mitigated.

After reading this account of Kolipinski's work, I began immediately to prepare some of the substance which he terms "Sodium Digitalate," because I realized that such a preparation would be of great medicinal value if Kolipinski's assertions were correct.

Allen's digitalis leaf was taken, exhausted with ether, the ethereal extract dried by spontaneous evaporation and the residue dissolved in a minimum of sodium hydroxide solution. The strength was adjusted by the addition of water so that the finished solution contains the ether extraction of 10 gms. of dried digitalis leaf in 100 cc., (same strength as the U. S. P. twelve). A specimen of this liquid is here shown and you will notice that the color is green with a brownish tinge.

A sample of the ether-exhausted powdered

leaf is also shown, together with a tincture made from 10 gms. of the ether-exhausted leaf of the strength of the U. S. P. tincture. Owing to the claims of my business, I have not been able to compare the physiological strengths of these preparations until to-night, when I hope to be able to show you how such experiments are performed.

In the interval since these preparations were made, there has appeared in the PHARMACEUTICAL JOURNAL, for March 14th, an article by Gordon Sharp, of Edinburgh, a noted physiologist, entitled "Digitalic Acid (Acid Resin) the Active Principle of the Digitalis Plant." Dr. Sharp had prepared preparations similar to those I have described. He tested the products on frogs and found that the solution of digitalic acid caused no stopping or slowing of the heart, in fact showed no action at all, whereas, the tincture prepared from the ether-exhausted leaf, stopped the heart within four hours, except in one frog, in which the beat was slowed to 3 to 5 a minute. Dr. Sharp intends to try the chemical action of these preparations, bearing in mind that pharmacological experiment is not always confirmed by the therapeutical effect. Until this has been done all that Dr. Sharp can say is, that pharmacological experiment fails to find evidence of toxicity or activity in the acid resin or so-called "Digitalic Acid" of Kolipinski.

Let us now try the effect of the solutions I have prepared, on some frogs and guinea pigs and find out for ourselves whether the ether extracts the valuable properties of the drug. Incidentally, you may be interested in seeing how this work is carried out. As you know, it is necessary to use a number of animals before it is possible to standardize a preparation with exactness. This is due to many causes, including the age, weight and sex of the animals, and so forth. Take the case of frogs. At this time they are waking up from the period of hibernation and they may or may not have quite reached a condition of normal physical activity.

The results confirm the report published by Dr. Gordon Sharp, in that the "Digitalic Acid" preparation appears to produce no effect whatever, while the preparation made from the marc, gives the typical action and toxicity of good digitalis."

Owing to the lateness of the evening, Mr. Haynes deferred reading his paper on spices and spoke briefly on the subject of the adul-

teration of Santonica. He stated that several samples had recently come to his attention which contained no true Santonica, probably due to the scarcity and consequent high price of the genuine, another article having been substituted entirely. The false article resembles very closely Santonica and is probably from a closely related species of *Artemisia*. A microscopic examination shows the false flower-heads to be a little smaller, greener, and more stemmy than Santonica. The odor and taste are seemingly identical with the true drug. Upon examination with the microscope the false sample shows distinctive and apparent differences from Santonica. A chemical examination of the spurious article yields little or no santonin, the largest amount obtained being but one-fourth of one percent.

Samples of Santonica and the adulterant, were exhibited in which the members were greatly interested.

EDWIN L. NEWCOMB,
Secretary N. W. Branch A. Ph. A.

On Monday evening, April 27th, Prof. E. L. Newcomb, the Secretary of the Northwestern Branch, gave a lecture before the Ramsey County Medical Association on crude drugs, their production and valuation. He pointed out the many difficulties encountered in collecting or growing medicinal plants of good quality and warned his hearers that the cultivation of medicinal plants was not the bonanza that the lay press had represented. Plant enemies, bad seasons, lack of experience in sowing and harvesting and other causes militated against the grower of herbs in his efforts to produce good drugs.

A fine collection of growing plants and dried drugs was shown, the latter illustrating the great need for the exercise of care in a druggist's purchases, by contrasting good and bad specimens of important drugs, such as: *Belladonna Folia*, *Digitalis*, *Stramonium*, *Rheum*, *Aconitum*, *Gentian*, and others.

Dr. Newcomb described the work of the students at the School of Pharmacy of the University of Minnesota, especially in the growing of medicinal plants and the harvesting of them in proper condition for the laboratory or dispensing counter.

The Chairman, Dr. Ritchie, invited a discussion on Dr. Newcomb's paper, in which several physicians and druggists joined, including Drs. Savage, Renz and Gilfillan, and Messrs. Rietzke and Frost.

Dr. Savage thought that the physiological standardization of vegetable drugs was of vital importance, especially when the effect of the drug was alike on the lower animals and man.

Dr. Renz spoke of the importance of having prescriptions filled by pharmacists who were well informed and capable of supplying medicines in the best possible condition.

Dr. Gilfillan congratulated the speaker on his admirable discourse, and expressed the hope that this evening would not be the last one devoted to so important a subject. He wondered how many druggists took the pains to keep such drugs as digitalis in good condition, free from moisture, and other deteriorating influences.

Mr. Frost replied that druggists were very much alive to the importance of buying good drugs and storing them properly.

Mr. Rietzke expressed his pleasure in being present at this "get together" meeting of St. Paul physicians and pharmacists.

After adjournment of the meeting refreshments were served.

COLUMBUS.

The first steps in the formation of a local Branch, in Columbus, were taken at a meeting of a number of the prominent pharmacists of this vicinity, including those from the Government Post, in response to an invitation from the Acting Editor of the JOURNAL to meet him at lunch at the Chittenden Hotel on May 27.

This invitation was heartily responded to, and the feeling was evinced that the formation of a Branch in Columbus, the home of the JOURNAL, had been too long deferred; that immediate action should be taken to form a local organization and that efforts should be made to secure the adhesion of a sufficient membership. The meeting adjourned to be called together at a later date.

On the evening of June 5, the druggists of the vicinage were the guests of Professor George B. Kauffman, in the Dutch room of the Hotel Chittenden. After the serving of a bountiful repast, Mr. Marshall called the meeting to order and stated the object of the gathering. He then called for the nomination of a temporary chairman, and Professor Kauffman was elected to that position, Mr. Edward Spease being selected as Secretary *pro-tempore*.

Mr. Kauffman accepted the duties of temporary presiding officer in a ringing speech, stimulating to the loyalty of the members of the A. Ph. A. and also to their fealty to the city of Columbus. It was time he said "to get out and get under" this movement. The journal of the Association, the leading pharmaceutical organ of the country, was edited, printed and published in this city, and every druggist and every citizen in Columbus should be proud that this fact made their city the center of pharmaceutical light for this country, if not for the entire world. Ambition and duty alike, called for them to make earnest effort to show their appreciation of the honor now conferred upon their home-city and to endeavor in every way to retain that

PROF. GEORGE B. KAUFFMAN

honor. During his remarks he paid a gracious tribute to C. Lewis Diehl, "the father of American Pharmacy." He said that he was in communication with the Chamber of Commerce of the city in regard to the retention by it of the proud position it now enjoyed, relevant to American Pharmacy.

Mr. Marshall called attention to the work of Dr. Beal in establishing the JOURNAL upon a firm foundation and to its extensive circulation. By means of it, Columbus was known to every civilized country on the globe, as the JOURNAL is on file in the great libraries of the capitals of Europe, and its pages were scanned from Syria to Canton, China. As was once said of England's banner, "the sun never set

upon it," so it might be as well said that the sun was ever shining upon the open leaves of the JOURNAL!

Mr. Topping moved that a Branch be formed, and it was so ordered. A committee was appointed to present the petition to the Honorable Council of the Association, praying for permission to establish a Branch in this vicinity.

A tentative organization was effected by the choice of Mr. George B. Topping, Ph.C., President; Edwin N. Webb, Vice President; Edward Spease, Ph.C., Secretary; Ernest C. Marshall, Ph.G., Treasurer, and Professor George B. Kauffman as Council Representative. The petition for the formation of the Branch has been brought before the Council and appears in the Council letters of this issue.

It is hoped that this organization will unite all the druggists of Columbus and its vicinity into one strong organization to work for the mutual good of the profession in the district comprised within its zone of influence.

College and Society

THE N. A. R. D. CONVENTION.

The annual meeting of the National Retail Druggists' Association in Philadelphia, the week of August 17th, promises to be a most interesting one in the way of entertainment for all those who attend the Convention.

The entertainment program comprises the following special features: The Officers' Reception and Grand Ball, which will take place in the magnificent ball-room at the Bellevue-Stratford Hotel on Monday evening, August 17th; an automobile sight-seeing tour is scheduled for the ladies on Tuesday, and on Wednesday, they will be the guests at a reception to be held at the John Wanamaker's store. Thursday will be "Scottissue Day," when the delegates will be taken on a steamer-excursion, by way of the Delaware river, to the model paper-plant of the Scott Paper Company, and on the return of the delegates, a stop will be made at the League Island Navy Yard for its inspection. Friday will be "Wampole Day," and the Convention will be the guests of Henry M. Wampole & Co. at Willow Grove Park. An elaborate dinner

will here be served to all members. There is no prospect of any visitor to the Convention being afflicted with ennui or nostalgia during the gathering, for the Committee has left no moment disengaged in the program they have planned. In connection with the meeting the exhibits at the Convention will be of much interest and attraction.

<>

PACIFIC COAST.

The regular monthly meeting of the Women's Pharmaceutical Association of the Pacific Coast was held May 22, 1914, in the Assembly Hall, Pacific Building, San Francisco. Mrs. R. E. White was in the chair.

A large attendance was present. Discussions were held on "A Method of Preparing Solution for Testing Purity of Nitrous Oxide Gas;" "A New Method of Filling Santal Oil Capsules;" "Improved Blaud's Pills," and "Prescription Pricing."

The President appointed the following delegates to the Annual Convention of the California Pharmaceutical Association: Miss Della Crain, Santa Cruz; Mrs. E. Goodman, San Francisco, and Mrs. E. E. Patterson, San Jose.

Mrs. Philip read a paper entitled "A Clerk." The discussion of the evening was on "Laboratory Methods."

<>

COMMENCEMENT OF THE COLLEGE OF PHARMACY OF THE UNIVERSITY OF THE STATE OF NEW JERSEY.

The Commencement of the Department of Pharmacy of the University of the State of New Jersey, for the classes of 1913-14, took place at the Masonic Temple in Jersey City, on the evening of June 2d, President Hon. James E. Pope presiding. The invocation was delivered by the Rev. Harry L. Everett, the Chaplain of the University, and the address on behalf of the University was given by Joseph E. Bernstein, the Treasurer.

The principal address of the occasion was made by Geo. M. Beringer, of Camden, N. J.; the President of the A. Ph. A. In his usual genial manner, President Beringer gave some of the history of pharmacy and advised the young graduates to be proud of their profession and to follow the example which has been given them by their teachers. He urged them to become members of the A. Ph. A.

and thereby to benefit themselves as well as to lend a helping hand in the evolution of pharmacy.

Hon. William H. Speer, Judge of the Hudson County Circuit Court, then delivered a short address. Dr. Joseph Koppel, Dean of the Department of Pharmacy, spoke on the great many improvements which have been made in the buildings and the equipment of the College, and also in the reorganization of the Faculty. He conferred the Degree of Graduate in Pharmacy (Ph.G.) on seventeen (17) students, and the Degree of Doctor of Pharmacy (Phar. D.) on thirty-two (32) students, the latter being dignified with the Doctor's hood.

President James E. Pope awarded the following prizes: The gold medal to Joseph S. Churgin, the silver medal and the silver cup for the best examination in Organic Chemistry to Herman H. North, both of the Senior Class, and the bronze medal to Jacob Feinberg of the Junior Class. The Post-Graduate prizes consisted of three (3) memberships in the A. Ph. A., and were awarded by Prof. Otto Raubenheimer to the following students: Isaac Friedman, for the best thesis in Chemistry, namely, "Arsenic in Household Articles;" Eugene Gordon, for the best thesis in Physiological Chemistry, namely, "Seminal Fluid," and Isidor A. Saphiro for the best thesis in Pharmacy, "Phenol and a Few of Its Derivatives."

Prof. Luke C. Hines, Secretary of the Faculty, read the Honor Roll of the Post-Graduates and Seniors. Herman H. North, in an elegant manner, delivered the valedictory address of the Senior Class, and Meyer A. Feinberg delivered an excellent address in behalf of the Post-Graduate Class.

The musical and vocal talent was supplied by the Malkin Music School of New York, and was highly appreciated. After the exercises, refreshments were served and the large audience was well pleased with the Commencement.

May 18th was a gala day at the College of Pharmacy of this institution when Prof. Joseph P. Remington addressed the students on "The Graduate's Opportunity." This address was given to the graduating classes, the members of which, undoubtedly, will profit by the good advice given by the professor. The speaker made the recommendation that pharmacists and physicians should go hand-in-

hand for the mutual protection of the public. He advocated the practice of more professional pharmacy and less of commercialism.

Prof. Remington's lecture was highly appreciated by all his auditors and especially by the students, who greeted him with cheers and college cries which were specially prepared for the occasion.

Dr. Joseph Koppe, Dean of the College, announced at the same time the names of those students who successfully passed the examinations.

The College year has been a very successful one, inasmuch as the Post-Graduate class consisted of fifty (50) students, and the Senior class twenty-five (25).

LOUISVILLE COLLEGE OF PHARMACY.

On Tuesday, May 12th, this institution completed its forty-fifth year with Graduation Exercises at the Woman's Club. Diplomas were awarded to twenty-nine young pharmacists, the degrees being conferred by President Simon N. Jones.

The College Medal was awarded to Sterling T. Monroe for best general average, and the Voigt & Co. Medal to S. Elbert Nichols for second honors.

The Peter-Feat-Richardson Medal was awarded to Wm. Orville Patterson for best general average in the Junior Class.

ILLINOIS PHARMACEUTICAL ASSO- CIATION.

With the slogan of "A week-end at Fox Lake" as a rallying cry, the Illinois Pharmaceutical Association assembled at the meeting of their State Association, June 11th, 12th and 13th, and had a very successful convention. For the first time in many years the Association had selected a summer resort for the place of meeting, and that the experiment was a success was the expression of practically all of the three hundred or more druggists and traveling-men who attended the convention.

The usual opening addresses were dispensed with. The Association listened to an excellent address by President Ralph R. Dorland, which, as well as the skillful manner in which he handled the convention, was widely commented upon. He especially urged druggists to get into politics, to make themselves felt as a political factor, to the end that the in-

terests of pharmacy might be conserved in both state and national legislation. He urged the formation of local organizations, and the cordial support of the two great national associations—the A. Ph. A. and the N. A. R. D. He thanked the members for their generous assistance to the officers in carrying on the Association's work during the past year and made a strong plea for a wider co-operation among pharmacists, especially in view of the need for anti-narcotic legislation and the powerful opposition that had developed. He urged that the Illinois Pharmaceutical Association be made an all-year-round organization and that its activities be not limited to the few days of the annual convention and the semi-annual session of the Executive Committee. He recommended the maintenance of permanent headquarters and the employment of an organizer to recruit the membership and interest the druggists in the work of the Association. President Dorland's address was received with applause and was referred to a committee consisting of W. S. Denton, O. C. Nusele and James H. Wells.

The report of the Secretary, W. B. Day, concluded with the presentation of 133 new members who were elected. This is the largest accession of members in many years.

Treasurer Garver's report showed an income for the year of \$1765.68 and expenditures of \$1914.39. There was \$600.00 in the permanent fund and \$1260.63 in the general fund at the close of the fiscal year, May 31, 1914.

Chairman Byron Armstrong of the Committee on Trade Interests, presented an excellent report and strongly endorsed legislation aimed at the establishment of a system of one-price to all on trade-marked and branded goods.

Chairman Charles Brunstrom presented the report of the Legislative Committee, which was devoted chiefly to plans for the coming year when the Legislature will again be in session.

Secretary Potts of the N. A. R. D. made a stirring address and offered resolutions regarding the unfair practice of cutting prices on standard goods, commending the Stevens Bill and pledging the earnest support of this Association. These resolutions were unanimously adopted.

Other reports were made as follows: For the Committee on Propaganda, Lee M. Pedigo, Chairman; for the Committee on

Druggists' Home, George W. Sohrbeck, Chairman.

Resolutions were adopted endorsing the National Association of Retail Druggists and continuing affiliation with that Association, also resolutions commending the U. S. Pharmacal Company.

Awards of prizes for essays were made as follows: First prize, J. A. Mahaffy, "The Advertising Value of Your Window"; second prize, to H. N. Bruun, "Advertising Schemes."

The following nominees were selected for presentation to the Governor for his consideration in appointing a member to fill the next vacancy on the Board of Pharmacy: J. B. Michels, El Paso; Robert Clarkson, Springfield; Lee M. Pedigo, Chicago. To the President of the University of Illinois for appointment of a member of the Advisory Board to fill the next vacancy, the following were selected: Jos. F. Shreve, Jacksonville; J. C. Wheatcroft, Grayville; Joseph Hottinger, Chicago.

Officers for the ensuing year were elected as follows: President, W. F. Baum, Danville; Vice-Presidents, Julius Riemenschneider, Chicago; W. S. Denton, Beardstown; Byron Armstrong, Jacksonville; Secretary, W. B. Day, Chicago; Treasurer, Christian Garver, Bloomington.

UNIVERSITY OF ILLINOIS SCHOOL OF PHARMACY.

The new catalog of the University of Illinois School of Pharmacy is now ready for distribution. A copy may be had by addressing the Actuary, W. B. Day, 74 E. 12th Street, Chicago.

Announcement is made of an increase in the entrance requirements beginning with the session of 1916-17 to graduation from high school of accredited grade or the full educational equivalent of this. The present entrance requirements for the shorter course which leads to the degree of Graduate in Pharmacy are two years of high school of accredited grade or its full educational equivalent.

For entrance to the longer course, leading to the degree of Pharmaceutical Chemist, graduation from high school is already required.

Entrance examinations, conducted by the Registrar of the University, will be held at the College of Medicine, Congress and Ho-

nore Streets, Chicago, September 21st to 25th, and will include all the high school branches in which credits are accepted.

Mr. Andrew Scherer, an alumnus of the Class of 1875, has offered a prize of twenty-five dollars in gold to the senior student who attains the highest average in pharmacy.

The fifty-fifth session begins Tuesday, September 22d.

The longer course in the school of pharmacy, leading to the degree of Pharmaceutical Chemist, closed June 5th; the degree was conferred upon Paul Wright Edgett, Gennaro Dominic Lavieri, Albert Schreiner, Jr., George Stulik, George F. Vaupell and Edgar Philip Heidebreder.

The Advisory Board held its annual meeting at the School June 4th. There were present at the meeting, George O. Lescher, of Galesburg; A. G. C. Ackermann and Herman Fry, of Chicago, as well as the faculty of the School.

The Chicago Veteran Druggists' Association has presented to the School the silver loving cup which was presented to Albert E. Ebert in 1995 and which, upon his death, reverted to the C. V. D. A.

<>

MASSACHUSETTS STATE PHARMACEUTICAL ASSOCIATION.

At the annual meeting of this Association held in June, the following officers were elected: Frank J. Campbell, President; John T. Harper, Great Barrington, William Hardie, Fall River, P. J. Fitzpatrick, Wellesley, Vice Presidents; James F. Guerin, Worcester, Secretary; James F. Finneran, Boston, Treasurer; William F. Sawyer, Boston, Edward A. Mole, Adams, James W. Cooper, Plymouth, Trustees of the Permanent Fund; Elie H. La Pierre, Cambridge, Delegate to the State Board of Trade.

Messrs. John J. Tobin, John F. Hayes and George J. Carroll were nominated for the Board of Pharmacy, and Prof. Charles F. Nixon, W. S. Flint and E. F. Leonard were nominated for the Board of Health.

OHIO STATE UNIVERSITY.

COLLEGE OF PHARMACY.

Commencement exercises were held in the Gymnasium on Wednesday, June 17, 1914. Six candidates for the degree of Bachelor of Science and 16 candidates for Certificate of Pharmaceutical Chemist were presented to the President by Dean George B. Kauffman.

The College of Pharmacy being an integral part of the University, its graduates participate in the general exercises of Commencement with the graduates of the other schools and stand in the same relation to the University as do all other of its graduates. The following are those who received the degree of Bachelor of Science in Pharmacy, with the titles of their theses:

Otto Carl Blum, Portsmouth, thesis, "Methods for Detecting Ethyl and Methyl Alcohol"; John Clinton Bowman, Thornville, thesis, "Outline for the Analysis of Sugar"; Robert Bruce McCann, Columbus, thesis, "Rapid Methods for the Separation of Alkaloids"; Earl Aloysius May, Van Wert, thesis, "Lead Acetate in the Examination of Gum Resins"; Albert Reinhart Paar, Canton, thesis, "Tests for the Identification of Cocaine and its Substitutes"; Paul C. Slater, Mechanicsburg, thesis, "The Estimation of Small Quantities of Alkaloids in Medicinal Preparations."

Sixteen candidates were awarded certificates as Pharmaceutical Chemists.

A. PH. A. PRIZE MEMBERSHIPS.

The following gentlemen have been awarded nominations to membership in the A. Ph. A. from colleges and universities because of exceptional work:

St. Louis College of Pharmacy—Julius Blanton Linn, of Canton, Mo., for general scholarship.

Baylor University, School of Pharmacy—John Morgan Fletcher, Dallas, Texas, for best general average.

University of Oklahoma—Frank Bradley, of Noble, was awarded the Browne prize, and Ralph Hron, of Guthrie, and Clarence Nicholas, of Anadarko, the Barbour prizes.

University of Tennessee—John H. Grant, Jacksboro, The Fortune-Ward Drug Co., of Memphis prize, for highest grade in Chemistry.

PERSONAL MENTION.

Mr. Harry S. Noel, member of the advertising staff of Eli Lilly & Company, was married June 10th, to Miss Nellie K. Covert, of Indianapolis, at SS. Peter and Paul Cathedral, by the Rt. Rev. Bishop Chartrand. Mr. and Mrs. Noel are taking an extended wedding trip East and will visit Mr. Noel's parents at Williamstown, Mass. New York City, Albany, Ithaca and perhaps several other cities will be included in their itinerary. Mr. Noel is a graduate of the Albany College of Pharmacy and for two years was connected with the Druggists' Circular and is known to many readers of the drug journals as he has been a contributor to the journals from time to time for the past five or six years.

<>

Maurice Palais Schwartz, the Secretary of the Indiana Pharmaceutical Association, was united in marriage to Estella Cecilia Fox, daughter of Mrs. Isabella R. Fox, on Tuesday, the 26th of May last, at Indianapolis.

Council Business

COUNCIL LETTER No. 23.

PHILADELPHIA, May 26, 1914.

To the Members of the Council:

The following communication has been received from Harry B. Mason:

"I am just in receipt of the proposed programme for the 62d annual meeting—page 55 of Council Minutes. I want to protest against the way in which the two sessions of the Commercial Section have been separated by three days. I have been chairman of different sections on three or four occasions, and I have discovered that the minute you sacrifice continuity you sacrifice interest also. I was shoved in as chairman of the Commercial Section this year somewhat against my wishes, and since my appointment I have been endeavoring to get up a live, vital, interesting programme. I want, if possible, to make the Commercial Section a real asset, and to this end I plead for a fair hearing.

All of which is preliminary to this motion: that the second session of the Commercial Section be held on Wednesday morning at 9:30 instead of Friday morning at 9:30, and that the first session of the Section on Pharmacopœias and Formularies be changed from Wednesday morning to Wednesday afternoon."

Motion No. 36 (Amendment of Program for Sixty-second Annual Meeting). Moved by H. B. Mason, seconded by J. W. England (1) that the second session of the Commercial Section be held on Wednesday, August 26, at 9:30 a. m., instead of Friday, August 28, at 9:30 a. m., (2) that the second session of the Conference of Pharmaceutical Faculties be held on Wednesday, August 26, at 10 a. m., and (3) that the original program as amended by above be substituted for the program given under Motion No. 35.

E. Fullerton Cook, Chairman of the Section on Pharmacopœias and Formularies, is opposed to any change in time for the first session of his Section, and if there is no objection, the time allotted for this Section will not be changed.

The following letter has been received from A. H. Clark:

"I return an affirmative vote on the proposed program for the Detroit meeting. I sincerely hope that this program will be strictly adhered to, as I believe it is a long step in the right direction. I hope also that all the changes suggested by Mr. Mason in Council Letter No. 20 will be adopted, as I

am firmly convinced that such changes will lead to much improvement over the present proposed program for the Detroit meeting. With few exceptions, the proposed changes are so obviously, to me, the proper thing that argument seems unnecessary.

"There is one point I want to mention. No matter what the program is, how it is managed by the Council, whether it be short or long, whether there be conflicting sessions or not, there is one thing that soon or late must be done. That is this: Arrange your program before the meeting, publish it, *and then stick to it* at the meeting. What demoralizes the entire meeting, creating more confusion and dissatisfaction than all else put together, is the endless string of *changes* announced by the Local Secretary at the opening of every session. About the second afternoon of the meeting no one knows what the program is. This is the thing that must be done. The other things are really of minor importance."

The following communication has been received from Francis E. Stewart:

"In response to Letter No. 20, I am commenting upon some of the suggestions made by Harry B. Mason in his letter to the Council.

"Mr. Mason's suggestions on the whole are certainly excellent, but it would seem to me that possibly suggestion No. 5 should be modified in some way, that the Association may have the advantage of discussing important suggestions made in the reports of the committees. Suppose, for example, a committee on legislation or some other important subject makes a report which should be submitted to the general meeting for discussion and action; the suggestion No. 5 made by Mr. Mason does not provide in any way for bringing such reports before the house. The suggestion of the Committee might be of the greatest importance as relating to legislation pending in Congress, affecting in a vital manner the interests of the American Pharmaceutical Association, or of the pharmaceutical profession itself. The Committee making the report might have a very different opinion of the subject than the majority of the Association. I can even imagine a condition in which the Council itself might have a different opinion than the Association. How could such a subject be brought before the general meeting for discussion?

"In regard to Mr. Mason's suggestion No. 15, the Association would be perfectly safe to empower the general secretary to reject or reassign contributions as long as the present incumbent is retained in the secretary's chair, but it might be a very different matter if the secretary was a man of less judicial temperament and possibly biased for or against certain subjects that might be presented in papers for discussion by the Association. It would seem to me that no one person should have the power to reject a paper. This power should be vested in a committee very carefully selected by the Association, or the authority should be vested in the Council."

The following has been received from Lucius E. Sayre:

"Permit me to say I am in favor of the general principles suggested by H. B. Mason for injecting efficiency into the A. Ph. A., now needed to catch up with the modern ideas of effective and productive work.

"I should be sorry, however, to see the Section on Pharmacopoeia and Formularies discontinued. Even the *Materia Medica* and *Pharmacognosy* should be *tried out*.

"I am surprised that Mr. Mason did not suggest the discontinuance of the Historical Section, instead of the others mentioned. This section, while indeed very important, does not, to my mind, have the same element of productivity and efficiency in it as do the sections recommended to be dropped.

"I should be glad to have the Council consider seriously the recommendation of Mr. Mason and I, for one, would be glad to sacrifice some of my pet sections for the general good."

Motion No. 37 (Applications for Membership). You are requested to vote on the following applications for membership:

No. 161. Edgar Seiple LaWall, 626 Second St., Catasauqua, Pa., rec. by Charles H. LaWall and M. R. LaWall.

No. 162. Joseph Hugh Cooney, 499 Columbus Ave., Boston, Mass., rec. by John G. Godding and Theodore J. Bradley.

J. W. ENGLAND,
Secretary of the Council.

415 North Thirty-third Street.

COUNCIL LETTER No. 24.

PHILADELPHIA, PA., May 30, 1914.

To the Members of the Council:

The following communication was received from Local Secretary Seltzer with reference to program for sixty-second annual meeting of the American Pharmaceutical Association, after the issuance of Council Letter No. 23 (May 28, 1914), containing amendments by H. B. Mason and J. A. Koch to program:

DETROIT, MICH., May 28, 1914.

Mr. J. W. England, Secretary of the Council,
Philadelphia, Pa.:

DEAR SIR—At a meeting of the local committee called for the purpose of considering the program submitted in Council Letter No. 22, it was deemed advisable to suggest a few changes. As modified, the program would read as follows:

Monday:

- 9.00 A.M. Meeting of Council.
- 3.00 P.M. First General Session.
Meeting of Committee on Nomination.
- 7.30 P.M. House of Delegates.
- 8.30 P.M. Joint Reception of Presidents of A. Ph. A. and M. S. P. A., followed by ball.

Tuesday:

- 9.30 A.M. Second General Session.
First General Session M. S. P. A.
- 10.00 A.M. National Association of Boards of Pharmacy.
- 10.00 A.M. Ladies Shopping and Visiting.
- 1.30 P.M. Ladies Boat Ride to Bois Blanc Island and Supper.
- 2.00 P.M. National Association of Boards of Pharmacy.
- 2.30 P.M. Scientific Section (1).
Joint Session of Commercial Section and M. S. P. A. (1)
- 7.30 P.M. House of Delegates.
Meeting of Council.

Wednesday:

- 9.30 A.M. Section on Education and Legislation (1).
Section on Pharmacopœias and Formularies (1).
Commercial Section (2).
National Association of Boards of Pharmacy.
- 10.00 A.M. Conference of Pharmaceutical Faculties.
- 12.30 P.M. Luncheon of College Alumni.
- 2.00 P.M. National Association of Boards of Pharmacy.
- 2.30 P.M. Women's Section (1).
Section on Practical Pharmacy and Dispensing (1).
- 2.30 P.M. Scientific Section (2).
- 7.30 P.M. Meeting of Council.
Theatre Party for Ladies.
Smoker for Men.

Thursday:

- 9.30 A.M. Section on Education and Legislation (2).
 Scientific Section (3).
 Joint Session of Section Practical Pharmacy and Dispensing and M. S. P. A. (2).
 10.00 A.M. National Association of Boards of Pharmacy.
 1.30 P.M. Excursion for Everybody to St. Clair Flats.

Friday:

- 9.30 A.M. Historical Pharmacy (1)
 Section on Pharmacopœias and Formularies (2).
 Women's Section (2).
 2.30 P.M. General Auto Ride
 7.30 P.M. Reorganization of Council.
 8.00 P.M. House of Delegates.
 8.30 P.M. Joint Session of Section on Education and Legislation, A. C. P. F. and N. A. B. P.

Saturday:

- 9.00 A.M. Meeting of Council.
 10.30 A.M. Final General Session.

In submitting the above program, we desire to say that each item of the program was very carefully considered, and the changes made were found necessary to meet the conditions, as we find them, some of which are beyond our control. The only exception to this is our suggestion to revert to our former custom of having the First General Session at 3.00 p. m. Monday, and the House of Delegates at 7.30 p. m.

Our reason for offering this suggestion is that we fear that the General Session held at 7.30 will seriously interfere with the reception in the evening. Even if we succeed in transferring much of the work usually done in the General Session to the House of Delegates, the one and a half hours allotted will not be sufficient to do what is left, including the work of the Nominating Committee. But even supposing that it were possible to transact all this business in one and a half hours, this brings us right up to the moment of the opening of the reception, 9.00 p. m. Since the room in which the session is to be held is the one in which the reception is to be held, it will be necessary to clear the room for that purpose, which takes time, and furthermore those who are active in the work of the session are also prominent at the reception, and they will require some time between these two engagements for preparations.

It seems to the committee that it will require but little mathematical calculation on the part of anyone experienced in how things move at such times to come to the conclusion that to hold the First General Session at 7.30 p. m. will result in pushing the opening of the reception well into the night, and in fact spoil that function, which to some of the visitors is a very important one.

On the other hand, should the House of Delegates meet at 7.30 and find it necessary to continue its deliberations beyond the hour

of the reception, it could do so, as its officers are not the officers of the Association whose presence at the reception is necessary.

Inasmuch as a serious effort is going to be made to run our program on schedule time, let us not handicap ourselves in the start by making a schedule which it will be a mathematical impossibility to live up to.

I, therefore, move the adoption of the above program as a substitute for motion No. 35.

Yours very truly,
 (Signed) LEONARD A. SELTZER.

The above motion will be known as *Motion No. 38 (Substitute Motion for Motions Nos. 35 and 36)*. Do you favor the adoption of the same?

CAMDEN, N. J., May 28, 1914.

To the Members of the Council of the American Pharmaceutical Association:

GENTLEMEN—Council Letter No. 21 contains a proposition from the William S. Merrell Chemical Company to assign a patent on Antiseptic Leaves to the American Pharmaceutical Association. As this matter is presented in this letter, several conditions are named. These conditions should receive the most careful consideration by the members of the Council before the proposition is accepted.

The assignment of this patent of the William S. Merrell Chemical Company is to be effective only "so far as the Association is concerned, provided this form is made official." Further, the Association is requested to formulate a price protection plan.

The first of these conditions seems to indicate that the assignment is made for the purpose of securing official recognition for this form of bichloride antiseptic medication. The Committee of Revision of the United States Pharmacopœia have voted to introduce a Bichloride of Mercury Antiseptic Tablet in deference to the extensive use of such tablets and the necessity for a legal standard therefor. I doubt if the Bichloride Antiseptic Leaf has yet attained such popularity or use as to receive official recognition, and I do not know that such a proposition has been presented to the Committee of Revision. It is evident that the American Pharmaceutical Association could not insure the pharmacopœial acceptance of any form of medication and this should not be made a condition of the Association's acceptance of the assignment of the patent.

The second proposition introduces another complication. The courts have not looked favorably upon any of the plans evolved for maintaining prices and this does not appear to be a proper field of work for the American Pharmaceutical Association to engage in.

It is intimated that the proposition of the William S. Merrell Chemical Company is on a par with that of the Norwich Pharmacal Company. That the members of the Council may have a clear understanding of the difference, I will explain that in the several conferences between the officers of the Nor-

wich Pharmacal Company and your President and Vice-President Apple, it was made very clear that the American Pharmaceutical Association could not be induced to engage in any commercial enterprise; that its acceptance of the assignment of their patent could only be accepted by the Association for the purpose of "promoting the public welfare" in accordance with the objects and aims set forth in the Constitution. The proposition which the Norwich Pharmacal Company submitted is a clean, clear, free-will offering, not associated with any conditions. It was the voluntary relinquishment of rights in the invention for the humanitarian purpose of safeguarding human life. The only reservation made was the right of manufacture by the inventor to be enjoyed in common with other manufacturers under such regulations as the Association may adopt to protect its rights under the U. S. patent laws.

I have no personal interest in any of these forms of Mercury Bichloride medication and am only concerned that the acceptance of such proposition shall be without conditions that might involve the Association in controversies or lawsuits.

Yours respectfully,
(Signed) GEORGE M. BERINGER.

J. W. ENGLAND,
Secretary of the Council.

415 North Thirty-third Street.

<>

COUNCIL LETTER No. 25.

PHILADELPHIA, PA., June 11, 1914.

To the Members of the Council:

Motions No. 34 (Election of Members; Applications Nos. 124 to 160, inclusive), No. 37 (Election of Members. Nos. 161 to 196, inclusive), and No. 38 (Substitute Motion for Motions No. 35 and 36) have each received a majority of affirmative votes.

Professor J. A. Koch, Chairman of the Executive Committee of the American Conference of Pharmaceutical Faculties, asks that provision be made in the program adopted under Motion No. 38 for a meeting of the Conference on Tuesday evening, August 25, at 8:30 p. m., and, if there is no objection, this will be done.

The following communication has been received:

COLUMBUS, OHIO, June 7, 1914.
Council of the American Pharmaceutical Association:

GENTLEMEN—The undersigned, a Committee representing and appointed from a meeting of the pharmacists of Columbus, Ohio, and its vicinity, called for the purpose of such action, respectfully petition your honorable body for its approval of the formation of a Local Branch of The American Pharmaceutical Association in and about this city, to be known as the Columbus Branch of the American Pharmaceutical Association.

They respectfully represent in support of their petition that they have received the pledges of the following-named "members of the Association in good standing,"—in accordance with the provisions of Article 1, Chapter XII of the By-Laws of the Association,—that they are desirous that such a Branch shall be formed in this vicinity:

Ackermann, P. J., Columbus.
Ashbrook, C. S., Mansfield
Bagley, Anna G., Columbus.
Beal, J. H., Scio.
Creighton, Mary L., Scio.
Dye, Clair A., Columbus.
Fickhardt, F. L., Circleville.
Ford, M. N., Columbus.
Franklin, Peter P., Columbus.
Hansen, M. K., Columbus.
Harp, L. D., Columbus.
Harrington, E. W., Columbus.
Hatton, E. W., Columbus.
Howson, A. B., Chillicothe.
Hauenstein, Sidney, Bluffton.
Hoffman, C. O., Arcanum.
Johnson, R. V., Columbus.
Kauffman, George B., Columbus.
Markworth, O. S., Columbus.
Marshall, E. C., Columbus.
McClintock, C. W., Columbus.
Oole, Edward, Columbus.
Powell, Fred A., Circleville.
Reed, C. D., Pomeroy.
Spease, Edward, Columbus.
Topping, George B., Columbus.
Webb, E. N., Columbus.

The Committee believe, should this petition be granted by your honorable body, that good results will result from the formation of this Branch, and they pledge themselves to make it a credit to the Association and to American Pharmacy.

Trusting that this petition will be granted, we beg to sign ourselves.

Yours very sincerely,
GEO. B. TOPPING,
EDWARD SPEASE,
ERNEST C. MARSHALL,
Committee.

Motion No. 39 (Organization of Columbus Branch, A. Ph. A.) Do you approve of the organization of the Columbus Branch of the American Pharmaceutical Association?

J. W. ENGLAND, Secretary.

415 N. 33d St.

<>

COUNCIL LETTER No. 26.

PHILADELPHIA, PA., June 18, 1914.

To the Members of the Council:

Professor E. Fullerton Cook, Chairman of Section of Pharmacopœias and Formularies, sends the following communication:

"The Section on Pharmacopœias and Formularies of the A. Ph. A. has planned as a feature of the meeting in Detroit a exhibition of the new or modified U. S. P. and N. F. preparations. It is believed that the plan,

as outlined below, will materially assist in familiarizing pharmacists with the new preparations and at the same time check up the formulas to avoid errors which may otherwise creep into the new books.

It is proposed to ask a number of pharmacists to each prepare twelve preparations. The committee will provide uniform bottles and the complete formula will be pasted on each bottle bearing a type-written label, this label to have upon it, title, ingredients, and directions for making. These preparations will then be exhibited at Detroit and those who have made the preparations will be invited to send in suggestions or comments.

I am writing this to you at the suggestion of Professor Beal to ask the Council for permission to give this amount of publicity to the new formulas of the N. F., and also for an appropriation to pay for the necessary bottles, label, type-writing and transportation charges. The Board of Trustees of the U. S. P. have sanctioned the plan for the U. S. P. preparations and appropriated \$50, or such part thereof as may be necessary, for the expenses on the U. S. P. part of the work.

Will you kindly put this matter before the Council so that, if it is approved, I may proceed at once. The expense is estimated to be within \$50."

The appropriation is approved by the Committee on Finance. Do you approve of the appropriation? This will be regarded as *Motion No. 40 (Appropriation of \$50 or less to Section on Pharmacopoeias and Formularies)*.

With reference to the proposition of the Wm. S. Merrell Chemical Co. (Council Letter No. 21, 53), and its offer of assignment of a patent on Antiseptic Leaves to the American Pharmaceutical Association, and President George M. Beringer's comments on the same (Council Letter No. 24, 63), Professor Julius A. Koch, to whom the original communication was addressed, writes as follows:

"I do not think that Mr. Beringer's objections are well founded. The assignment has been made in identically the same form and wording as that used by the Norwich Chemical Co. in their assignment. The Merrell Co. merely asks, that if it is within the province or power of the American Pharmaceutical Association, that their efforts be used to protect the retail pharmacist. This is not contrary to the policy of the Association which has for its object the betterment of Pharmacy.

If you have not as yet received a motion to accept the generous offer of the Wm. S. Merrell Co., Dr. Beal has asked me to present such a motion in his name and I will second the same."

The motion submitted is as follows:

(1) *Resolved*, That the American Pharmaceutical Association accept the complete assignment of the patent rights of the Wm. S.

Merrell Chemical Co., in and to a design patent for a new, original and useful improvement in packages for Antiseptic Poisons, serial number 817,364, as tendered by the Wm. S. Merrell Chemical Co. in their communication to Professor Julius A. Koch, dated May 15, 1914, and presented in Council Letter No. 21.

(2) *Resolved*, That the American Pharmaceutical Association hold such design patent exclusively for the free use of the medical and pharmaceutical professions of the United States, without restrictions, except such as may be necessary to prevent possible abuse through use of the design for non-poisonous substances.

(3) *Resolved*, That the American Pharmaceutical Association hereby tenders to the Wm. S. Merrell Chemical Co. a vote of thanks for their generous and public spirited offer.

The above will be regarded as *Motion No. 41 (Assignment of Patent Rights for Improved Package for Antiseptic Poisons)*.

The following communication has been received from Mr. Martin I. Wilbert:

"In the Bulletin of Pharmacy for June, 1914, Mr. Harry B. Mason publishes a copy of a letter to you in which he makes certain suggestions in regard to prospective changes in the meetings of the American Pharmaceutical Association. In a general way I wish to heartily indorse the suggestions and will endeavor to outline as nearly as possible my thoughts in regard to practical changes that should be made at the present time or in the very near future.

As I see it, there is absolutely no reason why the American Pharmaceutical Association should not conclude its meetings in four days allowing the two additional days of the week for the meetings of the Conference of Faculties and the Association of Boards of Pharmacy. My suggestions for a program would be as follows:

Monday, 9 a. m., Council Meeting.

Monday, 2 p. m., first general session restricted to the annual address of the President and the usual preliminaries for the selection of members of the nominating committee.

Intermission of fifteen minutes for the selection of members of the nominating committee, reconvening the Association for the second general session. At this second general session, the reports of committees should be received and referred to either the Sections of the Association or to the Council.

Monday evening, 8 p. m., meeting of the nominating committee; 9 p. m., reception.

Tuesday, 9-12 a. m., simultaneous sessions of the Sections on Scientific Papers, Education and Legislation, Practical Pharmacy, and Commercial Interests.

Tuesday, 2-5 p. m., simultaneous sessions of all Sections.

Tuesday evening, 8 p. m. to (?) a. m., meeting of the Council.

Wednesday, 9-12 a. m., simultaneous sessions of all the Sections.

Wednesday, 2-5 p. m., simultaneous sessions of all the Sections.

Wednesday evening, 8 p. m. to (?) a. m., meeting of the Council.

Thursday, 9-12 a. m., simultaneous sessions of all Sections.

Thursday p. m., concluding session of the Association, report on the proceedings of the Council, followed by adjournment.

It would, of course, be immaterial whether the meetings opened on Monday, Tuesday or Wednesday, the important matter being to concentrate the meetings and to eliminate the useless frills.

A program along the lines suggested would involve considerable pruning that would, I think, materially improve the proceedings of the Association. It would eliminate, among others, the Section on Pharmacopœias and Formularies, which I believe is quite unnecessary. Personally, I would prefer to restrict the activities of the Association to three Sections and to eliminate the so-called Section on Commercial Interests. The commercial interests of the pharmacist are either practical pharmacy or they are not pharmaceutical at all, and if not pharmaceutical have no room and no place in the American Pharmaceutical Association. The discussion of profitable sidelines, whether of the lunch-counter type, of the chicken-feed variety, or fake jewelry have little or nothing to do with pharmacy and should not be recognized in an organization designed primarily to discuss pharmaceutical problems.

My program would also eliminate the House of Delegates which has no legitimate room or place for existence, and in view of the fact that the Council already contains some thirty-eight or forty members with provisions for a further increase, I am inclined to believe that the latter body is quite sufficiently representative of the membership at large to take care of any business that may be referred to it.

One provision that I would like to see adopted in connection with the work of the Council is the recognition of alternates for members of the Council who are unable to attend the annual sessions. With a provision for alternates all sections of the country in which real live pharmacists can be found would be adequately represented and the members at large could readily intrust any business of the Association to such a representative Council.

This program also eliminates the so-called Women's Section which, as I understand, is not legally a part of the Association at the present time. While there can be absolutely no objection to an official or non-official Women's Auxiliary, there is, as I understand it, no provision in the constitution or by-laws of the Association that provides for election or recognition of non-members of the Association as members of a Section or as officers of a Section.

I most heartily endorse the proposition to

insist that a full and complete program of all the communications to be presented be prepared in advance so that the members present at a meeting will know exactly what they may expect. I would even go further, however, and limit the number of papers to be presented at any one session and insist that time be allowed for discussion. If such a program is prepared and lived up to, I am sure that the members present at a meeting will be in a position to be benefited by attending the Section sessions which offer the most interesting material and the meetings of the Association will tend to the further elimination of unnecessary duplication.

I quite agree with others that meetings of the American Pharmaceutical Association should be devoid of what has been referred to as "gabfests" and should be restricted to the consideration of really worth while material that will be a credit to the Association and make for progress in the sciences of our calling."

J. W. ENGLAND,
Secretary of the Council.

415 N. Thirty-third Street.

The Pharmacist and the Law

PHARMACY LAW OF PORTO RICO.

LEY

PARA ENMENDAR LA SECCION 6 DE LA "LEY AUTORIZANDO LA ORGANIZACION DE UNA JUNTA DE FARMACIA," APROBADA EN 8 DE MARZO DE 1906, Y ENMENDADA 10 DE MARZO DE 1910.

Decretase por a Asamblea Legislativa de Puerto Rico:

Sección 1.—Que la Sección 6 de la "Ley autorizando la organización de una Junta de Farmacia," aprobada en 8 de marzo de 1906 y enmendada en 10 de marzo de 1910, se entienda redactado como sigue:

"Sección 6.—Los individuos que estudien en Puerto Rico la carrera de farmacia deberán presentar antes de recibir su licencia, certificación firmada por un licenciado en farmacia, haciendo constar que ha practicado en su oficina de farmacia por un periodo no menor de dos años. Deberán examinarse de las asignaturas comprendidas en el siguiente plan de estudios:

Primer curso.—Química Inorgánica Física, Higiene, Historia Natural (Botánica, Zoología y Mineralogía).

Segundo curso.—Química Orgánica, Fisiología, Materia Médica o Farmacéutica Ani-

mal y Mineral, Materia Médica o Farmacéutica Vegetal.

Tercer curso.—Práctica de Operaciones Farmacéuticas y Reconocimiento de Drogas, Estudio de la Farmacopea de los Estados Unidos, Toxicología e Incompatibilidades."

Sección 2.—Toda ley o parte de ley que se oponga a la presente queda derogada.

Sección 3.—Esta Ley comenzará a regir desde su aprobación.

Aprobada, 7 de marzo de 1912.

TRANSLATION.

To amend Sec. 6.—This Law authorized the organization of a Council in Pharmacy. Approved on the 8th day of March, 1906, and amended on the 10th day of March, 1910.

"Decreed by the Assembly Legislative of Porto Rico."

Sec. 1.—That Sec. 6—of the Law authorizing the organization of a Council in Pharmacy approved on the 8th day of March, 1906, and amended on the 10th day of March, 1910, that the following methods shall be adopted.

Sec. 6.—Those individuals who study in Porto Rico the profession of Pharmacy shall find it a duty to present, before receiving his license, a certificate signed by a licentiate in whose Pharmacy he has practiced for a period of two years, and he must also pass examinations in the following studies:

First Course.—Inorganic Chemistry, Physics, Hygiene, Natural History, including Botany, Zoology and Mineralogy.

Second Course.—Organic Chemistry, Higher Physics, Chemistry, Materia Medica, Animal, Mineral and Vegetable Pharmacology.

Third Course.—Practice in the operation of Pharmacy and be able to identify the different drugs; also in the study of the Pharmacopoeia of the United States, Toxicology and Incompatibilities.

Sec. 2.—The whole Law or part of the Law that is opposed at present is waiting amendment.

Sec. 3.—This Law begins to govern after being approved.

Approved, March 7, 1912.

THE PORTO RICO COUNCIL OF PHARMACY.

President—Pedro Julia, San Juan.

Secretary—Jose Monclova, Rio Piedras.

Treasurer—Ramon L. Daubon, San Juan.

Members—Clemente Ramirez, Manati; J. Calderon Aponte, Catano.

Meetings:—

January, March, April.

June, September, November.

LIABILITY OF DRUGGIST FOR CLERK'S MISTAKE.

Action was brought for death caused by taking tartar emetic given the deceased in mistake for cream of tartar. The answer denied the authority of the assistant to sell drugs. The defendant, who was a practicing physician, was in partnership with another in the drug business. His time was principally devoted to the practice of his profession, and his partner looked after the drug store. The firm employed a clerk, about 18 years of age, who was not a registered pharmacist. The deceased, with her brother, drove to the store, where, at her request, the brother asked the clerk, who was alone in the store, for 10 cents worth of cream of tartar. The clerk by mistake gave him tartar emetic, wrapping it up in an ordinary paper package, without a label. She drank this dissolved in water, and died in consequence. There was no proof that the deceased's brother, when he entered the store, knew, or had any reason to surmise, that there was any limitation on the clerk's authority. If one enters a store, the court said, and finds a person apparently in charge, in the absence of notice to the contrary, he has a right to presume that such person is authorized to sell any ordinary article of merchandise kept for the purpose of sale, and to rely upon upon his procuring and furnishing the article asked for. It is a matter of common knowledge that there is a class of chemical preparations such as bicarbonate of soda, chloride of lime, copperas, and cream of tartar, which, while in one sense drugs, are in such general use for domestic and other purposes as often to be sold in general stores in the smaller towns, and which require no special skill or knowledge. Even though the clerk disobeyed his instructions, it is a settled principle that a master is liable for the consequences of the negligent conduct of his servant, committed in the course of his employment, although the particular act complained of was unauthorized by the master, and was done in disobedience to his commands.

Judgment for the plaintiff was affirmed.

Moses v. Mathews, Nebraska Supreme Court, 146 N. W. 920.

SALE OF STOCK OF DRUGS—FRAUD— CANCELLATION.

Lewis and Rea entered into a written contract by which Lewis was to trade Rea certain lands and \$2,100 for a stock of drugs. Lewis delivered a deed to one tract of the land, and paid Rea \$1,000 in money, and took possession of the goods. While running the store, and perfecting title to the other lands, Rea fraudulently obtained possession of the stock, and refused to proceed further with the trade. Lewis sued for rescission of the contract, cancellation of his deeds, and a return of the money he had paid. Lewis did not, however, offer in his petition to restore to Rea a small amount of money received by him on the sale of drugs, etc., while he was in possession of the store. It was held that, as Rea had in his hands moneys paid by Lewis on the contract far in excess of the money Lewis had received, it was not vitally necessary that an offer to restore be stated in the petition.

Rea v. Lewis, Oklahoma Supreme Court, 139 Pac. 977.

UNITED STATES PUBLIC HEALTH SERVICE.

List of Changes of Stations and Duties of Commissioned and Other Officers of the United States Public Health Service for the seven days ended May 20, 1914:

Assistant Surgeon-General L. E. Cofer. Granted 3 days' leave of absence from May 20, 1914. May 19, 1914.

Senior Surgeon S. D. Brooks. Detailed to accompany the Health Officer of Los Angeles, Cal., on inspection of Owens river water supply system. May 19, 1914.

Surgeon L. L. Williams. Detailed to attend the meeting of the American Medico-Psychological Association, to be held at Baltimore, Md., May 26-29, 1914. May 16, 1914.

Surgeon C. P. Wertenbaker. At the request of the Secretary of the State Board of Health of Vermont, detailed to attend the meeting of the Vermont Health Officers' Association to be held at Bellows Falls, Vt., May 21, 1914. May 13, 1914.

Surgeon H. S. Cumming. Detailed to attend the meeting of the Oyster Growers' and Dealers' Association of North America at Atlantic City, N. J., May 19-20, 1914. May 12, 1914.

Surgeon Carroll Fox. On request of the

State Board of Health of Minnesota, directed to proceed to that State to make, in co-operation with that board, an investigation of sanitary administration in Minnesota. May 12, 1914.

Passed Assistant Surgeon R. E. Ebersole. Granted 7 days' additional leave of absence from May 21, 1914. May 18, 1914.

Passed Assistant Surgeon H. M. Manning. Granted 10 days' leave of absence from June 3, 1914. May 14, 1914.

Assistant Surgeon D. C. Turnipseed. Granted 7 days' leave of absence enroute to station. May 18, 1914.

Assistant Surgeon M. V. Safford. Directed to proceed to Quincy, Mass., to investigate suspected case of typhus fever. May 18, 1914.

Sanitary Engineer Joseph A Le Prince. Directed to proceed via Washington, D. C., to Erie, Pa., to make an inspection of Presque Isle in respect to the prevention of disease-bearing mosquitoes thence via Washington, D. C., to Raleigh, N. C., for duty in connection with malaria investigations. May 14, 1914.

BOARD CONVENED.

Board of commissioned medical officers convened to meet at the Bureau, on call of the Chairman, to prepare questions for the written examination of Pharmacist C. Stier to determine his fitness for promotion to the grade of Pharmacist of the first class. Detail for the Board: Assistant Surgeon-General W. C. Rucker, Chairman; Passed Assistant Surgeon Hugh de Valin, Recorder. May 18, 1914.

Official:

RUPERT BLUE,
Surgeon-General.

List of Changes of Stations and Duties of Commissioned and Other Officers of the United States Public Health Service, for the seven days ended June 3, 1914:

Assistant Surgeon-General W. C. Rucker. Detailed to attend a meeting of the Surgeons' Association of the Baltimore and Ohio Railroad at Washington, D. C., June 18-20, 1914, and deliver an address on the subject of "Railway Sanitation." May 27, 1914.

Directed to proceed to Charleston, S. C., and deliver an address before the graduating class of the Medical Department of the University of South Carolina, June 4, 1914. May 27, 1914.

Surgeon J. A. Nydegger. Detailed to represent the Service at the annual meeting of the Medical and Chirurgical Faculty of

Maryland at Baltimore, Maryland, April 28-30, 1914. April 25, 1914.

Surgeon M. J. White. Directed, at the request of the State Board of Health of Kansas, to attend the annual conference of health officers to be held at Rosedale, Kansas, during the week beginning June 8, 1914, for the purpose of delivering a series of lectures on public health subjects. May 27, 1914.

Passed Assistant Surgeon W. H. Frost. Granted 1 day's leave of absence, May 31, 1914, under paragraph 193, Service Regulations. May 31, 1914.

Passed Assistant Surgeon E. H. Mullan. Directed to proceed to Baltimore, Md., about June 2, 1914, for the purpose of assisting Surgeon J. A. Nydegger in the examination of 1700 aliens due to arrive about that time. May 28, 1914.

Granted 10 days' leave of absence, on account of sickness, from May 12, 1914. May 26, 1914.

Passed Assistant Surgeon R. A. Herring. Granted 5 days' leave of absence from June 1, 1914. May 26, 1914.

Passed Assistant Surgeon J. R. Hurley. Detailed in addition to other duties, to assume the position of Superintendent of Hygiene and Sanitation Exhibits in the Departments of Education and Social Economy of the Panama-Pacific International Exposition. May 26, 1914.

Assistant Surgeon M. H. Neill. Granted 6 days' leave of absence from May 26, 1914, under paragraph 195, Service Regulations. May 25, 1914.

Assistant Surgeon J. H. Smith, Jr. Directed to report to the Superintendent, School of Instruction, Fort Trumbull, New London, Conn., for duty on Revenue-Cutter "Itasca" during the summer. June 3, 1914.

Assistant Surgeon John Sundwall. Directed to proceed from Lawrence to Rosedale, Kansas, in time to deliver lectures before the Annual School of Health Officers of Kansas, June 8-10, 1914, on the subject of pellagra thence to Washington, D. C., and report to the Director of the Hygienic Laboratory for duty. May 27, 1914.

Pharmacist J. V. La Grange. Granted 5 days' leave of absence from May 25, 1914, under paragraph 214, Service Regulations. May 25, 1914.

List of Changes of Stations and Duties of Commissioned and Other Officers of the United States Public Health Service, for the seven days ended June 10, 1914:

Assistant Surgeon-General J. W. Kerr. Detailed to attend the meeting of the Massachusetts Medical Society at Boston, Mass., June 9-10, 1914, for the purpose of presenting an address on the relation of physicians to public health organization and administration. June 6, 1914.

Surgeon P. M. Carrington. Granted 12 days' leave of absence from June 8, 1914. June 3, 1914.

Surgeon G. B. Young. Granted 1 year's leave of absence, without pay, from July 1, 1914. June 6, 1914.

Surgeon B. W. Brown. Directed to proceed to Boston, Mass., and assume charge of the Marine Hospital at that port. June 6, 1914.

Surgeon T. Clark. Directed to proceed to Ellis Island, N. Y., and report to the Chief Medical Officer for the purpose of familiarizing himself with methods followed in making examinations for mental disorders. June 4, 1914.

Surgeon L. L. Lumsden. Upon completion of preliminary sanitary survey in Lawrence County, Indiana, directed to proceed to Mississippi, with the force under his charge, for the purpose of making a similar survey of Union and another county of that State. June 3, 1914.

Surgeon John F. Anderson. Directed to proceed to Wilmington, N. C., and Savannah, Ga., for inspection of Service operations in field investigations of the public health. June 5, 1914.

Surgeon W. C. Billings. Granted 3 days' leave of absence from June 5, 1914, under paragraph 193, Service Regulations. June 4, 1914.

Surgeon J. Goldberger. Relieved from duty as member of board on new "Nomenclature of Diseases." June 5, 1914.

Surgeon J. W. Schreschewsky. Relieved from duty as recorder of board on new "Nomenclature of Diseases." June 5, 1914.

Passed Assistant Surgeon R. H. Creel. Directed, at the request of the Efficiency and Economy Committee of Illinois, to proceed to Springfield and other points in that State to make an investigation of sanitary administration and the laws under which it is conducted. June 6, 1914.

Passed Assistant Surgeon R. E. Ebersole. Granted 7 days' leave of absence from June 3, 1914, under paragraph 195, Service Regulations. June 4, 1914.

Passed Assistant Surgeon A. D. Foster. Upon completion of sanitary inspections in South Carolina, relieved from duty at Marine Hospital, New Orleans, La., and directed to proceed to Washington, D. C., and report to the Bureau for temporary duty. June 2, 1914.

Passed Assistant Surgeon N. Roberts. Directed to proceed to Philadelphia, Pa., and report to Senior Surgeon Fairfax Irwin for temporary duty in fumigation of vessels at that port. June 3, 1914.

Passed Assistant Surgeon E. R. Marshall. Relieved from duty at Honolulu, Hawaii, and directed to proceed to Providence, R. I., and assume charge of the Service at that port.

Changes of Address

All changes of address of members should be sent to the General Secretary promptly.

The Association will not be responsible for non-delivery of the Annual Volume or Year Book, or of the JOURNAL unless notice of change of address is received before shipment or mailing.

Both the old and the new address should be given, thus:

HENRY MILTON,

From 2342 Albion Place, St. Louis, Mo.

To 278 Dartmouth St., Boston, Mass.

Titles or degrees to be used in publications or in the official records should be given, and names should be *plainly* written, or type-written.

THE LEGISLATIVE PROBLEMS OF PHARMACY.*

JAMES H. BEAL, SC. D., LL. D.

Our forefathers placed their trust in an over-ruling Providence; the present generation relies mainly upon the legislature.

Our grandparents believed that the best method of meeting the difficulties of life was by the cultivation of the habits of thrift, economy and self-reliance, and that the proper remedy for social evils was the development of higher standards of citizenship, and an enlarged appreciation of the individual's duty to the state: now we are taught that the various difficulties of human life can be eliminated, and all the ills of society cured, by act of Congress or General Assembly.

The American system of commonwealths was established upon the theory that the best government was that which afforded the citizen the largest field for individual initiative and the most untrammelled opportunity for working out his own ideals of prosperity and happiness. So far have we drifted from this ancient and wholesome doctrine, that we are now attempting to make each citizen a ward of the state, and to guard and direct his every act and ambition, as if he were an irresponsible and heedless infant. We are piling statute upon statute, adding bureau to bureau and official to official, until the liberty of individual action and the responsibility of the citizen, are becoming obscured in a maze of artificial duties and scheduled prohibitions.

For morals we are beginning to substitute the provisions of statute law; and

*An address delivered before the North Carolina Pharmaceutical Association, June 17, 1914.

for the dictates of conscience, the arbitrary rulings of some autocratic bureau-official.

The American people have become possessed of a perfect fury for legislating. No matter what the difficulty, whether of a particular class or of the body politic, whether economic, social or moral, whether the temporary difficulties, arising from the changing forms of industry or commerce, or the permanent difficulties due to the inherent qualities of human nature, the first, and almost the only thought, is to appeal to the law-making bodies for relief.

No member of any legislature can find the time to even read, much less to digest and understand, the provisions of all the measures upon which he is asked to vote, each one of which, if enacted, would seriously affect, in greater or less degree, the liberty and possessions of every citizen of the state.

The modern social-industrial-commercial system constitutes an enormous complex which defies comprehension or analysis. Every new law introduces new wheels and cogs, the ultimate effect of which upon the existing complex, it is impossible to foresee, which often throws "out of gear" some of the most useful parts of the social machine, these dislocations calling for fresh amendments, so that the legislation-mad reformers are continuously chasing themselves around a circle of their own blunders.

Granting that our highly complex society needs more regulation than the comparatively simple social organization of a century ago, it cannot be denied that the annual flood of new laws is far beyond reason or necessity.

The courts are clogged with the consideration of cases involved in an entanglement of obscure and frequently contradictory statutes, and then we prate about "the law's delay" and the "uncertainties of justice," when properly our censure should be directed to our system of machine-made jurisprudence that no finite intelligence can reconcile or understand.

While every occupation and industry is more or less adversely affected by this hasty and ill-considered legislation, our own particular calling happens to be one that offers especial and peculiar opportunities for legislative attacks. Drugs and medicines are things of mystery to the unlearned, who cannot comprehend how the same substance can be either harmless or dangerous, a messenger of health or an agent of destruction, according to the manner of its use; and it is this popular prejudice which makes it so difficult to combat the efforts of bucolic statesmen who seek to bridle us with ridiculous and useless provisions.

The wrong use or misuse of a drug is always more widely advertised than its proper and lawful use. The countless thousands of cases where drugs are properly and beneficially employed are never heard of, while the comparatively few cases of misuse are heralded far and wide until the reading public is lead to believe that such misuses are of constant and regular occurrence, a situation which affords the savior-of-the-race-by-legislation-reformer the opportunity he most delights in, and serves as the excuse for the composition of bills which would either totally prohibit the sale of useful drugs or else impose such restrictions upon their sale as to amount in fact, if not in name, to practical prohibition.

If it were proposed to prohibit the sale of edged tools because they are sometimes the source of injury to careless users or may be employed for homicidal

purposes, the inadvisability of punishing the many for the doubtful protection of the few would be apparent to every one, yet the cases of accidental injuries from drugs or of their homicidal uses are probably much fewer in number than those which follow the general distribution of knives and razors.

Singularly enough, these restrictive measures frequently seem to be aimed especially at the druggist, regardless of how much of the same products may enter the hands of the public through other sources. Some years ago, while comparing the poison laws of the various states, I discovered that some of them applied in terms to druggists only, i. e., that while druggists were subjected to certain restrictions in the sale of poisonous substances, all other dealers were exempt from these requirements. Even now there is pending in Congress a bill which would impose very onerous conditions upon the dispensing of mercury bichloride by licensed physicians and druggists, but which would place no restriction whatever upon its sale by other persons, or in other words, the men whose learning and experience best qualify them to handle the substance with safety to the public, are to be hampered, while unqualified dealers are to be left free to do as they please.

As druggists, we do not pretend to claim that our business interests should be preferred to the public safety, nor do we object to *reasonable* and *efficient* regulations regarding the sale of poisons or dangerous drugs. What we do object to, are the half-baked efforts of hysterical reformers, who are unable to comprehend that the measures which they propose, would interfere needlessly with the proper and legitimate use of such articles, without abating the evils at which they are supposed to be aimed.

Unfortunately for our peace of mind, the signs of the times point to even more attempted drug-legislation in the future than in the past.

Since the enactment of the Federal Food and Drugs Act—for which, by the way, the drug trade was largely responsible—the regulation of the sale of drugs and medicines, has been recognized by the politicians as a legislative “soft snap,” i. e., they have discovered that it is easy to appeal to popular prejudice, by proposing to legislate against some alleged enormous evil resulting from the sale of certain drugs, which alleged evils may be altogether imaginary or else molehills magnified by the sensational press to mountainous proportions.

Their perception that food- and drug-legislation affords a cheap and easy path to glory, has also been stimulated by their discovery that the drug trade has been willing to accept a tremendous amount of punishment, without striking back at its punishers, a kind of prey which the demagogue especially delights to pursue.

For the drug trade, legislation is no longer an academic subject that may be debated pleasantly at the annual convention, and then dismissed until the next meeting, but it is a live and vital topic which demands vigilance and aggressiveness throughout the year, if we are to avoid the gradual imposition of burdens that will, at length, make business conditions intolerable.

We cannot prevent the constant flinging into the legislative hopper of all sorts of meddlesome legislation, but must rely upon our efforts to prevent its enactment or to secure its proper amendment, and in many cases we shall discover that the only appropriate amendment is the classic one “to strike out all after the enacting clause.”

It is time that the drug trade should abandon its usual apologetic attitude when attacked in the legislature or by the sensational press, and demand proof for the asserted necessity for additional restrictive legislation. All drug legislation that does not originate with the State Pharmaceutical Association, or with its legislative committee, should be opposed on general principles. In other words, our attitude should be one of general hostility to all drug legislation proposed by outside interests, until its propounders have demonstrated its absolute necessity, that the demand for it is not based upon exaggerated and sensational reports which have no substantial foundation in fact, and that the restrictions to be imposed will bear *equally upon all* who handle or deal in the same or similar products, and not merely upon the class of dealers who happen to be known as druggists.

Not only must we present strenuous opposition to unnecessary new restrictive drug legislation, but it is equally incumbent upon us to seek the correction of the imperfect and sometimes inconsistent measures, which our past inertness and lack of interest have permitted to be placed upon the statute books.

The Poison Laws.—In some states, in addition to that which is specifically known as the poison law, there may be two or three, or a half a dozen other acts, relating to particular poisonous drugs, overlapping each other in their provisions. In some cases the confusion is so great as to make it impossible to decide which law should apply in a given case, as compliance with one, may make the druggist liable for the violation of another.. These laws should be consolidated and rewritten, and made so specific, that there can be no doubt as to their scope and application.

One consideration frequently overlooked when poison legislation is proposed, is that the bulk of lethal agents employed in the arts and in agriculture, immeasurably exceed the amount of the same or of similar agents handled by the druggist. Where the paint stores sell tons, the druggist sells ounces. If the existing laws make any distinction between lethal agents sold in the drug store and those sold elsewhere, the discrimination should be removed. If the druggist may sell poisons only on physicians' prescriptions, then the paint store and general dealer should be restricted in like manner.

Since almost any drug or chemical that is sufficiently active to serve as an effective therapeutic agent, will also be active enough to injure, if used to excess, there is always room for the fanatical reformer to declare it dangerous, and to propose legislation to prohibit its sale. If some check is not placed upon legislation of this sort, the drug-store shelves will soon be little better than a historical museum of the drugs which we were once permitted to sell.

The Anti-Narcotic Laws.—Closely connected with the poison laws, and frequently forming a part of them, are the laws relating to the sale of habit-forming narcotic drugs. Like the former, they are often a patchwork of overlapping statutes and incomplete. In some directions they may be needlessly restrictive, and in other directions not restrictive enough. Where they do not already do so, they should be amended so as to restrict the handling of these drugs to legitimate channels, i. e., to the licensed pharmacist and physician, and a complete and accurate method for tracing the purchase and sale of the drugs should be provided

In this connection, we should guard against the disposition of those misinformed reformers, who would extend the list of habit-forming drugs to include nearly everything in the Pharmacopœia. Because a man has learned from experience that a particular remedy, most certainly, relieves him from a recurrent ailment or symptom, so that he commonly or "habitually" uses it, in preference to other remedies for that ailment, by no means renders it a habit-forming drug. To call such drugs habit-forming, is a mere play upon the words *habit* and *habitual*. It is doubtful if a drug can properly be called *habit-forming*, unless it is one the repeated use of which induces a craving, which only the drug will satisfy, its repeated use not being to relieve the ailment or symptom for which it was originally taken, but to relieve a condition which the use of the drug itself has created.

It may or may not be good policy to restrict the liberty of the citizen to select his own remedies, but it can scarcely be regarded as a proper policy to place restrictions upon popular remedies, by definitions specially created to suit the particular case, or by the verbal trick of calling them "habit-forming drugs."

Neither does it necessarily follow that the presence of a minute proportion of a habit-forming drug, constitutes a habit-forming drug of the mixture in which it is found. If the proportion of the drug present, is sufficient to create the drug-habit, when the use of the mixture is long continued, or if the amount is sufficient to satisfy a habit already existing, then the combination can properly be placed in the category of habit-forming drugs, otherwise not. The question is one of fact in every instance, and can be answered only by an impartial consideration of the evidence.

Both pharmacy and medicine are interested in legislation respecting the sale of habit-forming drugs, and representatives of both, should participate equally in the framing of such measures, and in appearing before committees of the legislature, to defend or oppose narcotic legislation when necessary. In fact, I might go farther, and say that physicians and pharmacists should coöperate in like manner upon all measures which deal with matters of joint interest to their two professions.

It is undeniable that a certain percentage of both doctors and druggists have been interested in the illegitimate traffic in habit-forming narcotic drugs, but it is monstrously unjust to charge either doctors or druggists with general participation in such traffic. It is only the exceptional physician who is careless in the prescribing or dispensing of these drugs, and only the exceptional pharmacist who desires or encourages the patronage of *habitues*.

But whether responsible or not for narcotic drug evils, both the conscientious physician and the conscientious pharmacist must give up some of his just prerogatives and must submit to some inconveniences in order that the traffic may be brought under proper control.

If the law is so liberal in its provisions as not to inconvenience the legitimate dispenser, it will not restrain those who participate in the illegitimate traffic, and if made sufficiently drastic to insure the detection and punishment of the latter class, it is bound to cause some occasional hardship to those who dispense narcotic drugs legitimately. As is always the case in the restraint of crime, the just

man must give up some of his liberty, in order to supply the means for the discovery and punishment of the criminal.

In this connection, it is well to have in mind the fact that the evils due to the improper use of narcotic drugs, have been enormously exaggerated. On an actual census of the *habitues* in almost any section, the "hundreds of victims" of the yellow press, will dwindle to dozens or even less. In one small community where an agitator asserted that there were at least fifty victims of the drug-habit, careful inquiry among doctors and druggists, developed the existence of two morphine *habitues* and a suspected third, without the discovery of a single user of cocaine. Doubtless the percentage of victims would run higher in some other communities, but, in most cases, we could safely deduct 90 percent from the stories of the sensational press, and still cover all of the cases discoverable by an exact census, and furthermore, in districts where the cases were most numerous, it would be discovered that the drugs were distributed, mainly, by persons who have no connection with either pharmacy or medicine, and whose supplies are obtained from a distance, through underground channels.

As a matter of course, we do not want to be responsible for even a few victims of the drug habit, but pharmacists and physicians should certainly defend themselves from the reckless charges, of wholesale debauchery of the public through habit-forming drugs, that have been disseminated by hysterical reformers and the sensational press.

The General Food and Drug Laws.—The food and drugs acts, or the statutes which fix the definitions and prescribe penalties for the adulteration and misbranding of foods and drugs, are, generally speaking, fairly satisfactory to the drug trade, that is their defects are rather those of detail than of general principles.

Perhaps the greatest defect of the state food and drug laws, is their lack of agreement with each other and with the Federal law of 1906. While following the same general pattern, no two of them are exactly alike in particulars. These differences, especially as to labeling requirements, are a constant annoyance, and occasionally may become a serious menace, to the retailer. The jobber or manufacturer, having labeled his products in accordance with the Federal law, may ship them into any state regardless of state law, but, after they have left the domain of interstate commerce, the products come under the control of the local statutes, and the retailer may be held liable, if they do not conform thereto. When propositions are made to amend these laws, the drug trade should see to it that they are brought more nearly into conformity with the Federal law, and should strongly resist all amendments that would tend to increase their present discrepancies.

Although representatives of the drug trade played a prominent part in the drafting and enactment of the food and drugs acts, one of the things which they evidently failed to foresee, was the importance of making a distinction between actual adulteration and a mere variation from the legal standard, without connivance or guilty intent on the part of the dealer.

The popular understanding of adulteration, is the addition of a cheaper substance to a more expensive one, as the addition of water to milk, or the withdrawal of a valuable constituent, as the removal of cream, both processes being

for the purpose of increasing the profits of the dealer at the expense of the consumer. By definition, however, any variation from the standard constitutes an adulteration, even if the quality of the product be superior to the standard fixed by law. The druggist who should sell genuine imported bay rum, would be guilty of selling an adulterated drug, because the standard of the law happens to be a fictitious bay rum. Thus the druggist may be legally guilty of fraud, when morally innocent, or morally guilty of fraud, and legally innocent. Again, nature frequently produces drugs of alkaloidal strength below the legal standard. The drugs are genuine, though deficient in strength, but if the dealer disposes of them as genuine, he is, legally, guilty of adulteration. Numerous other examples might be cited, where one might be held guilty under the law, when his acts were entirely devoid of evil intent.

Undoubtedly, fixed standards of quality should be established and enforced, but the *definition of the offense* should be altered, so that the dealer in drugs who innocently sells goods which vary from the standard, will be punishable only for his actual fault, and will not be liable to the disgrace of an arrest and conviction, for an act which, in the public mind, always involves the element of moral turpitude.

That this defect has not occasioned more hardship to the drug trade than it has, is due to the fortunate presence in the law of the so-called "variation clause," which permits the sale of articles which vary from the official standards, provided the variation is stated on the label.

If the variation clause should ever be repealed, as has been proposed, the situation would then become one of serious menace to the entire drug trade, for, under such conditions, it would be practically impossible to conduct a drug business without constant technical violations of the law.

Another serious defect of the food and drugs act, is that they fail to provide the means whereby the manufacturer or dealer may ascertain, in advance, that his labels are in accordance with the law, or, rather, that they are in accordance with the administrative officer's interpretation of the law.

In numerous cases, there is so much room for difference of opinion, that no one can state in advance what the decision of the department may be. On more than a few occasions, the manufacturer, after the examination of precedents and the taking of legal advice, has labeled his product in good faith, only to be later haled into court, as a dealer in misbranded goods.

Generally the administrators of the law, when appealed to, will voluntarily give advice as to the labels which they will regard as legal, but they may refuse this advice if they choose, and some of them have done so. Every food and drugs act should, therefore, contain a provision specifically requiring the executors of the law to pass upon the sufficiency of labels submitted for inspection, and prosecutions for alleged misbranding should be restrained, until after dealers have been notified of the insufficiency of their labels and afforded an opportunity for their correction.

Laws Regulating the Practice of Pharmacy.—The general pharmacy laws, or those regulating admission to the practice of pharmacy, are, in most states, in need of a general overhauling. Most of them were in the nature of experiments when passed, and only time could demonstrate their imperfections.

As a rule, these laws provide for two grades of licentiates, a Registered or Licensed Pharmacist, who may conduct or manage a drug store, and a Registered Assistant, who may perform any of the work in a drug store, except to act as the responsible head or manager.

I believe that experience has demonstrated the advisability of at least one other grade of license, namely, that of licensed storekeeper, to be issued to the keepers of general stores, and stores in towns where no registered pharmacist is located, authorizing the holders of such licenses to sell such common household remedies as are specified by the Board of Pharmacy. The license should be issued for a small sum; should be renewed annually, and should specify the drugs and remedies which may be sold by the licensee.

Some druggists have been inclined to oppose the granting of such licenses, on the ground that it is a recognition of the right of unqualified persons to sell drugs. The answer to this objection is, that it is always wise to recognize an existing fact. Unqualified dealers, already, have this right under the law, and we are not likely to live to see a legislature that will take it away from them. The conversion of these dealers into a class of licensees by themselves, is a step towards bringing the sale of drugs by unqualified persons, under the control of the board of pharmacy, and we shall be foolish if we do not accept the opportunity if it is offered to us.

The most important licentiate is, of course, the Registered or Licensed Pharmacist, or the licentiate who is authorized to act as the responsible head of a drug store, either of his own or for another owner. If the responsible head or manager, the man who buys the goods, directs the daily conduct of the store, and determines the general policy of the establishment, is properly qualified in character, by education and experience, the public safety will be well guarded, and the main purpose of the pharmacy law accomplished.

Of late years the proposition to require graduation from a reputable college of pharmacy, before admitting candidates to examination for the license of Registered Pharmacist, or what has come to be known as the "graduation prerequisite," has become a question of importance. Several states, already, have such a requirement in the law, and several others have practically the same requirement, by virtue of a rule of the State Board of Pharmacy.

Naturally such an advance over the requirements once thought necessary, has provoked controversy.

One objection offered to making college graduation a requirement for registration, is, that it would tend to reduce the Board of Pharmacy to a subordinate position and make it subservient to the colleges, is an entirely unwarranted conclusion. Its effect would be exactly the opposite, because the Board would have power to name the requirements of the colleges whose graduates it would admit to its examinations, and the colleges would thus be brought under the direct and permanent control of the Board of Pharmacy.

Another objection which has been urged, is, that it should make no difference to the Board of Pharmacy how or where the candidate obtains his qualifications, provided he has them, and this is an objection the force and cogency of which cannot be denied. The fact remains, however, that there is no place and no method, for a complete and systematic training in the theory and art of pharmacy,

equal to that provided in a properly equipped and properly conducted college or school of pharmacy.

But cannot the Board, by its examination, ascertain whether the candidate has had the requisite systematic training? No, it cannot. Examinations have a useful and necessary place in the educational system, but they have their limitations. Mental growth or education, like physical growth, requires regularly supplied *pabulum* and proper exercise. The examination of a human stomach might determine what the subject had for his last meal, but it would not show that he had received the continued nourishment and exercise necessary to the production of a well-developed and properly-trained human body.

The board-examination may determine what the candidate has in his memory at the time of the examination, but it cannot, except to a very limited extent, ascertain whether this information was gained in such a regular and systematic manner as to render it probable that it has become a part of his permanent mental equipment or whether it is a medley of miscellaneous information gathered haphazard, and retained by a feat of memory.

Experienced educators recognize the fact, that even the final college-examination is not a sufficient test to prove that the candidate for graduation has gained the proper benefit from his college work, and, therefore, the student is tested from day to day and from week to week, and unless his daily and monthly record has reached the required standard, the result of his final examination will not secure him the coveted diploma.

My thesis is, that two kinds of training are necessary for such a complete and well rounded education of the future pharmacist as will make him a safe guardian of the public health, and a creditable representative of his profession, namely, a sufficient period of actual experience in the drug store and the systematic training of a reliable college or school of pharmacy. This statement is made with full recognition of the fact, that there have been many pharmacists who have been conspicuously successful without the benefit of college training, and also that there have been college graduates who have been conspicuous failures. The college cannot supply deficiencies in mind and character: it can only cultivate and train the qualities which are provided by the candidate, but the future pharmacist, who misses this training, will have missed something that would have added completeness and finish to his career, no matter how successful he may otherwise become.

Another argument offered in opposition to the graduation pre-requisite, is, that it would act as a deterrent to many who will prefer to take up some other occupation or line of business, on the ground that the rewards of pharmacy are at present not sufficient to justify the time and expense necessary to secure a college education.

This may be true, but if so, I do not see why the contingency should worry the present race of pharmacists. If no new drug stores should be started within the next quarter of a century, the existing ones would, very likely, be able to supply all the probable demands for drugs and medicines, and then, perhaps, the rewards of pharmacy would be sufficient to justify a college education.

It should be kept in mind that the graduation pre-requisite would not apply to those already qualified to practice pharmacy, but only to future candidates, and

also that it would not apply, either in the present or in the future, to clerks or assistants, but only to those who desired to become managers. Under a pre-requisite law, the non-graduate would have every opportunity to perform the functions of a pharmacist that he has now, except to become the responsible head or manager of a drug store.

The law would also, necessarily, have to allow a reasonable length of time before the graduation requirement went into effect, to permit the full registration of the non-graduates who were previously acting as clerks or assistants. In other words, the law would, in any case, apply only to those who in the future should desire to enter pharmacy, and not to those already within its ranks, whether proprietors or clerks.

This is a matter which each state must settle for itself, and it would be better to proceed too slowly than too quickly, or at least to proceed no more rapidly than is justified by the progress of sentiment among the pharmacists of the state, but it should be kept in mind that, to admit that college training is *desirable* for the preparation of the future pharmacist, is, in effect, an admission that it is to that extent a necessity.

The question is one which has two sides to it, and we should not be too dogmatic either way, but I believe the weight of argument is in favor of the graduation pre-requisite, and that the sooner it is universally adopted, the better it will be, both for the present generation of pharmacists and for those who come after them.

In this fragmentary and somewhat disjointed review, I have aimed to sketch, in a very broad outline, some of the legislative problems to which we must direct attention, and, especially, have I aimed to emphasize the thought that, as a general policy, we should oppose all additional restrictive legislation until convinced of its absolute necessity, either to correct existing laws or to enable us to meet the artificial conditions that these laws have created.

But whether we are to oppose or to support proposed new legislation, our only hope to do so successfully, lies in our ability to concentrate the efforts of a thoroughly united drug trade to that purpose.

The Needed Solidarity of Pharmacy.—One of the greatest needs of the drug trade—*perhaps its very greatest need*—is a more decided craft spirit, or craft consciousness; a clearer realization of the fact that all of those connected with the production, manufacture or distribution of drugs and medicines, constitute a solidarity, in which the interests of every unit radiate to every part, so that an injury to one is an injury to every unit within the circumference,—something like the *esprit de corps* that prompts the soldier to identify himself with the honor of the flag or the reputation of his regiment.

In times not long since, there was no more coherence in the drug trade than in a heap of sand, which changes its contour with every wind that passes over it. There was no fixity of purpose, and but little, if any, spirit of craft loyalty. The actual, if not expressed, motto was that of the trade corsair, "Every fellow for himself, and the devil take the hindmost"—which he usually did—and so successful was he in the capture of the rear guard, that the front ranks began to crowd a little closer together for mutual defense, which has brought about the condition of half-hearted organization that now exists.

Retailers, manufacturers, and wholesalers have all, at times, been ready to sacrifice the interests of each other, and of the members of their own class, for the sake of some temporary personal advantage. It must be confessed, with shame and humiliation, that the reason why the earnest attempts of some proprietors to protect the advertised retail prices of their goods, have not succeeded, has been that there have always been some retailers ready to betray their class by surreptitiously supplying the trade-demoralizing price cutter. During the past year a member of a concern which has been unable to buy certain proprietary articles from their manufacturers, told me he had no difficulty whatever in procuring abundant supplies through retailers who, openly at least, pretend to be supporting the proprietors' plans for price protection.

No policy can absolutely prevent the presence of traitors within the ranks, but a well-developed and constantly-stimulated spirit of Craft Loyalty will discourage treason, and minimize its effects, when it does occur.

The Necessity for United Action.—The experience of the past few years, should have convinced us, that we can hope to make headway against the flood of obnoxious legislation by which we are continually threatened, only by united and unanimous action all along the line, from the largest manufacturer and wholesaler, down to the smallest retail dealer in drugs.

The rivalries and differences, that have at times disturbed the peace between the several divisions of the drug trade, are petty and insignificant, when compared to the larger interests which they have in common, and nowhere are these common interests more in evidence, than in matters of legislation, whether state or national. Unless we can present a united front to the attacks of the sensational reformer, or of the notoriety-seeking administrative official, anxious to magnify the importance of his office by the discovery of mares' nests in the drug business, we can only expect to be beaten in detail.

Neither manufacturers, jobbers nor retailers acting alone, can successfully defend themselves from the destructive legislation of the hysterical reformer, nor from the attacks of the sensational press, which furnishes his ammunition. But each division of the trade can exert a force and influence of its own, and these forces and influences, when united, can be well nigh irresistible.

According to the ancient fable, when the woodman requested permission of the forest, to take a small tree to make a handle for his ax, the intended victim insisted strenuously upon its rights as a member of the community, but the big trees said, "It is only a miserable little sapling, let the woodman have it."

The ax was helved accordingly, and it was not long until the whole forest was prostrated, before the instrument, to the perfecting of which the rights of the insignificant sapling had been sacrificed.

Any branch of the drug trade which consents to the invasion of the just rights of the smallest and most insignificant members, either of its own or of any other branch of the trade, is consenting to a thing that is wrong in principle, and in the end must suffer a part of the penalty.

Section on Historical Pharmacy

Papers Presented at the Sixty-First Annual Convention

THE TABLET INDUSTRY—ITS EVOLUTION AND PRESENT STATUS.

L. F. KEBLER, PH. C., M. D.

Continued from Page 958, July Issue.

Puckner and Clark, and Puckner and Hilpert restricted their observations entirely to the determination of phenol in tablets of bismuth, opium and phenol. It is conceded by all that volatile agents of the phenol type should not be compressed into tablet form and that manufacturers should prepare such commodities only on special request. They should furthermore safeguard their reputation by placing upon the label a statement of the following character: "The amount of phenol declared to be present in each tablet according to label was used in their preparation, but on account of the volatile nature of phenol it is impossible to give any assurance as to the amount present in the finished product and it is supplied with this understanding." The results obtained by these workers are given herein, but they do not form a part of any general conclusion made here relating to tablets, except in so far as it may pertain to tablets containing volatile agents.

Seel and Friederich made the latest observations recorded in literature. They examined tablets of only three separate drugs and in one instance but two determinations were made. The results by these investigators, recorded in Table 9, are satisfactory. A large majority of the tablets examined contained less than the amount declared, but for all practical purposes they come within the 10 percent maximum variation from the amount declared upon the label.

do	1.0	.923	—7.7

From the results recorded by Liebreich fifteen years ago, and the observations of Seel and Friederich, a 10 percent maximum variation from the declaration upon the label would be satisfactory. But the observations made by other analysts militate against such a restricted standard. In order to obtain more extended data on this point, a large number of tablets of American make were examined and the results are recorded in Table 10. These results represent the average of ten or more tablets.

²Puckner, W. A., and Hilpert, W. S., J. Am. Med. Asso., 1911, 56: 1844.

⁴Seel, Eugen, and Friederich, Albert, Med. Klin., 1911, 7: 888, 928.

Variations more than 15 percent above declaration.....	16	3.6
Variations more than 20 percent below declaration.....	69	15.4
Variations more than 25 percent above declaration.....	11	2.4

COMMENTS.

The variations are unexpectedly large both in numbers and amounts. The tablets examined are of relatively simple composition, and, for the most part, contain medicinal agents which can be readily estimated with a fair degree of accuracy. The tablets examined are fairly representative of all manufacturers. In only a few factories were the finished tablets actually examined chemically. The best tablets were found in factories where competent chemical control exists. In fact, no excessive variations were found in several brands so supervised. A careful review of the tablets examined shows, with possibly a few exceptions, that all of the results should have fallen within 10 percent, either above or below, the declaration. To find over one-third exceeding this variation does not substantiate the old-time claims for accuracy and uniformity. Even on a 15 percent basis nearly one-fourth are wanting. There is no reasonable excuse for such deviations, for example, as the presence of twice as much corrosive sublimate as claimed. This simply shows gross carelessness and incompetence. It will also be observed that a much larger number of the results fall below the amounts declared than above. The methods of analyses may contribute to this in a few instances. It is claimed that this is the safest side to err on, but the factor of safety is frequently too liberal, for example, 20 percent or more below claim in simple tablets of acetanilid or acetphenetidin or aspirin savors either of gross carelessness or design. It should be noted that since this investigation was begun more competent control has been provided in a considerable number of establishments, and there are indications of general improvements.

TABLETS CONTAINING VOLATILE OR UNSTABLE AGENTS.

Although the tablets containing volatile or unstable drugs are comparatively small in number, they are sufficiently important to call for careful consideration. Agents coming under this classification are nitroglycerin, phenol, camphor, chloro-

form, ether, ammonium carbonate, various essential oils, etc. Except in a few cases the amount of work done is inadequate to warrant conclusions, but it is well known that medication of this character is difficult to prepare and keep. It is furthermore common knowledge that the fact that the tablets are right at the outset is no proof that they will long remain so. Medical men should not resort to such uncertain medication, as it reflects discredit upon the profession and tends toward drug nihilism. The writer has in his possession tablets containing camphor which is sublimed on the sides of the bottle. They are no longer suitable medicines. In the case of essential oils there is often only sufficient present to impart a flavor. The phenol variability has been pointed out by Puckner and Clark,¹ and Puckner and Hilpert.²

In the present investigation nitroglycerin tablets, for various reasons, received chief consideration. Nitroglycerin is one of the most powerful heart remedies, and is depended upon by physicians in cases of emergencies which are sometimes of a very serious character. It has been reported from time to time that nitroglycerin tablets are of uncertain character, and that even though they are originally made with the proper quantity of nitroglycerin, it is impossible to state or represent how long they will remain so. This uncertainty of nitroglycerin tablets has been charged to the supposed volatility³ of nitroglycerin. With this general knowledge available, whether correct or otherwise, it seems rather strange that some manufacturers should fill orders with nitroglycerin tablets made three or more years previously. Some manufacturers of deficient goods explained the shortage on the ground that the tablets had been on hand three, four or five years at the time the orders were filled. Yet in no instance did there appear any information on the packages to the effect that they were several years old. The packages, however, did bear the declaration that each tablet contained a given quantity of nitroglycerin. If such claims appear, they should be at least approximately correct. Such potent drugs should not be made on the hit or miss basis. A goodly number of the tablets on the market were purchased and examined, with the following results:

It will be noted that the determinations made by two separate and distinct methods gave fairly concordant results. The shortages recorded are based upon the highest results obtained by either of the methods. The deficiencies found are abnormally large. Notwithstanding the general belief (which does not appear to be well founded) that nitroglycerin tablets are prone to deteriorate with age, it is reasonable to expect that they should possess at least 75 percent of the actual value claimed for them. It is furthermore believed that a 25 percent deficiency is excessive. Even on this basis a large majority (78 percent) are wanting. Over 42 percent exceed a 50 percent deficiency. During the interviews it developed that the tablets were not generally analyzed. The 10 percent nitroglycerin alcoholic solution and 10 percent nitroglycerin milk sugar triturations used were apparently accepted as represented in most instances without question. Various experiments were made to determine how rapidly nitroglycerin tends to volatilize at room temperature in a vacuum desiccator. The results seem to indicate that nitroglycerin is not as volatile as is believed by some. Experiments made with nitroglycerin tablets thus far show that some at least are fairly stable. The subject is, however, still under investigation.

It should be stated that after this paper was read, the writer's attention was called to a report of a "Committee of Chemists appointed to investigate the possible deterioration of drug extracts," which report was said to contain useful information on the stability of nitroglycerin tablets. After some correspondence a copy of this private publication, dated December 31, 1908, was received. The results recorded are herewith submitted:

Nitro-Glycerin Tablets.¹

"We give below four samples assayed and re-assayed, and they do not seem to indicate any deterioration to amount to anything, and we know of no case of a nitro-glycerin tablet which failed to act physiologically, no matter how old it was. This seems to point to the fact that nitro-glycerin on milk sugar (which we know to be a good preservative and prevent oxidation quite largely) as it is used by physicians almost altogether, does not deteriorate appreciably with age."

—J. M. FRANCIS.

CONCLUSIONS.

1. Tablets are not as uniform and accurate as is generally believed.
2. There is little difference between the uniformity of the larger tablets produced by the single or multiple vertical punch or the rotary machines.
3. The vertical single punch delivers more uniform hypodermic tablets and so-called compressed tablet triturates.
4. There does not appear to have been much advancement in the manufacture of uniform tablets during the past twenty years, even though the machinery has been materially improved.
5. The number of tablets produced from a given quantity of material should not vary to exceed 5 percent from the number calculated.
6. The variation in weight of tablets should not exceed 8 percent, either above or below the average.
7. The variation from the declaration should not exceed 10 percent in the average tablet or tablets of a fairly simple composition.
8. In complex, very small and difficult tablets to manufacture the variation from the declaration may be as great as 15 percent.
9. Volatile agents should not be compressed into tablet form, excepting flavoring agents and possibly nitroglycerin under strict control.
10. The amount of talcum used should not exceed 5 percent.
11. Fillers such as fuller's earth, chalk, gypsum, terra alba, kaolin, etc., should not be used.
12. No insoluble or non-disintegrable tablets should be placed on the market.

METHODS OF ANALYSIS.

INTRODUCTION.

The methods given here have not reached the stage where improvement is impossible. They are offered as a basis for future work, and it is hoped that all interested in this line of analysis will not only assist in trying out and improving these methods but will devise new ones as time and opportunity permit.

The work in this article has been restricted to uncoated tablets. Some of the methods, however, will undoubtedly give satisfactory results not only with uncoated but with many coated tablets as well. Some skill and adaptation may be

*Report of Committee of Chemists, 1908, p. 4.

²Report of Committee of Chemists, 1908, p. 16.

necessary with the latter products. A casual review of the ingredients used medicinally and in giving form to tablets shows that extreme care must be exercised in devising analytical methods which will insure accuracy and reliability. The majority of compressed tablets containing insoluble agents usually contain starch, gummy material and some lubricant. Soluble chemicals are frequently compressed without excipient. Lubricants are, however, often employed. Molded tablets generally contain either sugar of milk or sucrose, or both, as a base. Some disturbing features are liable to creep in with the utmost circumspection. Checking and counter checking must be employed frequently. The chemical reagents used must be carefully tested. In preparing granulations the process may be such as to occlude some of the medicinal agents so that it is very difficult to remove them completely with the ordinary solvents from the powdered material. For example, if in the manufacture of caffeine tablets starch paste is used, some of the caffeine may be dissolved and intermixed with the starch paste which on drying, envelopes the caffeine and thus makes it very difficult to remove. In fact, in some instances it is virtually impossible to remove it completely. Starch and gummy material are great handicaps in formulating simple methods of analysis.

The analyst in the factory has a distinct advantage over the chemist not so connected. The former knows or can ascertain what breakers are ahead and may thus avoid them. Not so fortunate, however, is the chemist who simply has the tablets placed before him for analysis. For example, the factory chemist examines a sample of tablets and finds the results abnormal. He is unable to explain the difficulty, but the perplexity is readily solved when he calls for and receives the working formula. The analyst who has only the tablets to work from must depend upon his own ingenuity to solve and overcome various difficulties and it must be admitted that some of them may never be solved.

GENERAL METHODS.

WEIGHT OF TABLETS.

Weigh separately from ten to twenty-five tablets in order to ascertain the average weight and the variation from the average.

PREPARATION OF SAMPLE.

In a mortar, or other suitable apparatus, finely powder from ten to twenty-five or more tablets, mix thoroughly and introduce the powder into a weighing tube for future use. This procedure is not applicable to tablets containing volatile agents. It is of the utmost importance to powder finely and prepare a uniform sample.

DETERMINATION OF MOISTURE.

The amount of moisture may be determined in tablets containing non-volatile drugs by drying the powder in a vacuum (not less than 25 inches) at a temperature not exceeding 75° C. or in a hot water heated oven, to constant weight. These methods do not always give the same identical results, but they are sufficiently concordant for practical purposes.

DETERMINATION OF ASH.

Ignite a small portion at a dull red heat until the residue is white or gray, cool in a desiccator and weigh. Best results are secured in a well regulated muffled furnace. Flat platinum dishes are frequently used for this purpose. The analyst should, however, never employ a platinum dish for ashing drugs unless he knows there is nothing present which will injure the platinum. It is always safest to use porcelain or silica dishes. Hoskin's electric furnace is well suited for ashing.

ATOMIC WEIGHTS.

The international atomic weights for 1914¹ (oxygen, 16) are used in all calculations excepting methods of analysis in Bulletin No. 107 (revised). For Pharmacopœial articles (Eighth Decennial Revision) the atomic weights recognized by that authority (hydrogen, 1) must be used.

SPECIAL METHODS.²

The methods given below are designed chiefly for determining the active medicinal ingredients. No claims for complete analysis are made, but in some cases the examinations are made as complete as practicable with present experience.

ACETANILID TABLETS.

Acetanilid, Method A: Place from $\frac{1}{2}$ to 1 gram of the finely powdered material on small, double counterpoised filters, one within the other, in a funnel, and treat with successive portions of chloroform until all of the acetanilid is removed. From 40 to 60 cc. are generally sufficient. The solvent must be carefully applied, best from a pipette, not only to the powder directly, but to the sides and upper edges of the filters. Each addition should be allowed to drain before more solvent is used. When exhausted, wash the stem of the funnel with chloroform, collect the filtrate and washings in a tared Jena or non-sol beaker,³ evaporate carefully at a slightly elevated temperature or in a current of air until the solvent is apparently dissipated, add 5 cc. of ether, evaporate, then heat for 15 minutes at about 100° C., cool in a desiccator and weigh.

Comments: The chloroform will remove certain lubricants such as "white oil," cocoa butter, stearic acid, and, if present, will be found with the acetanilid residue. The amounts are, however, usually so small that they may be disregarded for practical purposes. This observation is applicable to other determinations where the same or similar conditions obtain. A Gooch crucible may be used to advantage in place of the filter papers.

Purity of acetanilid: The purity of the acetanilid can be determined by the Pharmacopœial standard for this drug. The most important single observation is the melting temperature. Pure, dry acetanilid melts at from 111° to 113° C. If there is not sufficient material, a larger amount of the powder may be extracted. Occasionally artificially colored tablets are encountered. In such cases the chloroformic residue may be correspondingly colored, but the amount of color dissolved is generally negligible.

¹J. Am. Chem. Soc., 1913, 35: 1809; Drug. Circ., 1914, 58: 28.

²With the collaboration of W. O. Emery, E. C. Merrill, A. G. Murray and S. Palkin.

³These beakers should be used in all similar determinations.

Acetanilid, Method B: If the acetanilid should prove impure, proceed by method A above, except collect the filtrate into a 200 cc. Erlenmeyer flask, distill to about 10 cc., add 20 cc. dilute sulphuric acid (10 percent) and digest on steam bath until the liquid is reduced to about 15 cc. and the chloroform is removed, then add 20 cc. of water, continue digestion until solution is reduced to about 15 cc., again add 20 cc. of water, continue digestion until solution is reduced to about 10 cc., finally add 40 cc. water and 15 cc. concentrated hydrochloric acid, and titrate with standard potassium bromid-bromate solution (Koppeschar's solution) until a slight yellowish color persists.

Comments: The first part of this procedure is for the purpose of converting the acetanilid into anilin sulphate and dissipating the acetic acid. The yellowish color is due to a slight excess of bromin. While adding the reagent the flask should be repeatedly rotated to agglutinate the precipitated tribromanilin formed. Should the amount of acetanilid be large and the tribromanilin precipitate too bulky, it may be necessary to dilute the anilin sulphate solution more and even titrate an aliquot part of the solution. If there is any probability of the chloroform dissolving sufficient water to carry appreciable amounts of associated bodies, the chloroform extracts should be collected in a second separatory funnel and washed with 15 or 20 cc. of water, then transferred to the Erlenmeyer flask and proceeded with as directed above. This observation should be borne in mind while working with various mixtures.

Potassium bromid-bromate solution: Dissolve 50 grams of potassium hydroxid in 50 cc. of water, add bromin, at ordinary temperature, to slight excess, dilute to 500 cc., heat to expel excess of bromin, filter, and make up to a liter. The solution is standardized against acetanilid and should be diluted so that each cc. represents about 0.01 gram of acetanilid.

Reactions involved in preparing potassium bromid-bromate solution and in determining the acetanilid by method B:

Residue insoluble in chloroform: The total residue can be ascertained indirectly by deducting the amount of acetanilid obtained from the original weight taken. It may also be determined as follows: (a) Expose filters and contents in a protected place to the atmosphere for 24 hours, then weigh, using outer filter as counterpoise. (b) Heat filters containing the residue at 100° C. for one-half hour, cool in desiccator, and weigh, using outer filter as counterpoise. This gives residue on a moisture-free basis. Suitable calculations must be made to reduce data to uniform basis.

Comments: The residue of compressed acetanilid tablets consists essentially of starch, adhesive matter and inorganic lubricant, but in the case of molded tablets it consists chiefly of milk sugar.

The kind of starch may be determined by means of a microscope. The amount of starch may be estimated by the official method described in Bulletin 107 (revised) Bureau of Chemistry, p. 53, beginning at the point where the insoluble

residue is introduced into the refluxing flask and heated with 200 cc. of water and 20 cc. of hydrochloric acid.

Ash: Proceed as directed by general method for ash. The inorganic matter should consist essentially of talcum, but occasionally some "filler" is met.

ACETANILID COMPOUND.

Tablets bearing this name should contain as medicinal agents, acetanilid, caffeine, and sodium bicarbonate, together with the ingredients usually employed in preparing tablet medication. The caffeine and acetanilid of this mixture may be extracted from a neutral, an alkaline or acid aqueous solution with chloroform.

Caffeine: Place about 1 gram, accurately weighed, into a separatory funnel¹ (A), add 25 cc. chloroform, shake well, add 25 cc. water and sufficient dilute sulphuric acid to render distinctly acid, agitate thoroughly and set aside for the chloroform to separate and clear. Transfer the chloroform to a 200 cc. Erlenmeyer flask through a small, dry filter. Repeat this operation with the same amount of chloroform three or four times, or until exhaustion is complete. Distill the chloroform gradually as the extraction proceeds to about 10 cc. finally. Then add 20 cc. of dilute sulphuric acid and continue distillation until all the chloroform is removed, transfer flask to steam bath and digest mixture until contents of flask are reduced to about 10 cc., add 20 cc. water and continue digestion until liquid amounts to about 10 cc.; cool, transfer to separatory funnel (B) with sufficient water to make about 25 cc. Exhaust with successive portions of chloroform (25 cc.) until all the caffeine is removed. The chloroformic extractions can be evaporated in a tared beaker at a low temperature or the chloroform may be distilled from a flask to about 10 cc., then transferred with washings to a tared beaker and evaporated spontaneously or at a low temperature in a current of air. When apparently dry, cool, add 5 cc. of ether and evaporate carefully to avoid loss of caffeine by crepitation, finally dry at 80° C. for one-half hour, cool in desiccator and weigh.

Comments: Test purity by U. S. P. standard for caffeine. Unless extreme care is exercised the results will be low, due to incomplete extraction, creeping, etc. In this operation the acetanilid is converted into anilin sulphate, which, like many alkaloidal salts, is insoluble in chloroform and other immiscible solvents and, therefore, remains in the solution from which the caffeine has been extracted.

Acetanilid: Transfer aqueous solution in separatory funnel (B) containing the anilin sulphate to an Erlenmeyer flask, wash the separatory funnel (B) and the filter used for filtering chloroformic solution of caffeine above with two successive portions (15 and 10 cc.) of water, and also introduce these washings into the flask. Heat flask containing the anilin sulphate a short time to expel the chloroform, add 15 cc. of concentrated hydrochloric acid, then introduce slowly a standard potassium bromid-bromate solution, with agitation, until a distinct yellow color persists. The amount of acetanilid can readily be determined from the number of cubic centimeters of standard solution used. See comments for acetanilid under acetanilid tablets.

Sodium Bicarbonate, Method A: Introduce into a suitable dish from ½ to 1 gram of the material, incinerate at a dull, red heat, until all organic matter is

¹The joint should be moistened with a drop of water to prevent leakage of chloroform.

destroyed and the residue is white, or nearly so; cool, dissolve the residue in water, add sufficient but a known amount of standard sulphuric acid to decompose the carbonate, then titrate back the excess of acid with standard potassium hydroxid solution, using methyl orange as indicator. Calculate results to sodium bicarbonate.

Comments: If the mixture is heated to fusion any talcum that is present may be disintegrated and the results obtained abnormal. This procedure is applicable only in special cases.

One cubic centimeter of normal sulphuric acid is the equivalent of 0.084 gram of sodium bicarbonate.

Sodium Bicarbonate, Method B: This chemical may be accurately determined by treating the mixture with 20 percent hydrochloric acid and absorbing the carbon dioxid evolved. About 2 grams of the material should be used. A detailed method with illustrated apparatus will be found on pages 169 and 170 of Bulletin 107 (Revised), Methods of Analysis, Bureau of Chemistry.

Comments: This method may be used in all cases where no other method is given.

Talcum, etc.: Introduce into a previously heated, cooled and weighed Gooch crucible provided with an asbestos mat about 1 gram, accurately weighed, of the powder; treat with sufficient warm water at about 40° C. to remove the sodium bicarbonate, etc., wash with 25 cc. alcohol, incinerate to white ash, cool in desiccator and weigh. The powder may be disintegrated in a beaker with water at about 40° C., then transferred to crucible and finished as above.

Comments: This procedure will include not only talcum but other insoluble, inorganic, non-volatile matter which may be added in the form of a filler or otherwise.

This general procedure may be used unless some non-volatile or insoluble (in water or alcohol) inorganic medicinal agent is present and should be applied when no other method is given.

Starch: Weigh into a 200 cc. beaker a suitable quantity, 2½ to 3 grams, of the dry material, add 50 cc. of alcohol, mix thoroughly, allow to stand a short time, transfer to filter and wash with about 200 cc. of lukewarm water, puncture the bottom of the filter, wash the residue into a 500 cc. flask with water, and make the volume up to 200 cc. with water, add 20 cc. of hydrochloric acid, specific gravity 1.125, attach flask to reflux condenser and heat for two and a half hours. Cool and nearly neutralize with sodium hydroxid, make volume up to 250 cc., filter and determine the dextrose in an aliquot part of the filtrate as directed in Methods of Analysis, Bulletin 107 (revised), page 49, section (b).

Comments: This method is of general application for ordinary starch, but is not suited for estimating soluble starch. Table for calculating dextrose will be found in Bulletin 107. Starch is present in virtually all tablets containing insoluble drugs and should be determined by this method.

ACETANILID COMPOUND WITH CITRIC ACID.

Citrated caffein is sometimes used in place of the alkaloid caffein. Some manufacturers seem to forget that there is a difference between the two products and furthermore they do not appear to know that this product should consist approximately of equal parts of caffein and citric acid. All of the ingredients present in these tablets excepting citric acid may be determined by methods given under acetanilid compound.

Citric acid: If there is no disturbing factor present, the acid can be titrated directly, but usually sodium bicarbonate is present in these mixtures and frequently sufficient moisture to induce some reaction with the citric acid forming a little sodium citrate. Several methods have been tried, but the results have not been concordant. Methods tried were: Extraction with absolute alcohol and titration; precipitation as barium citrate in 50 percent alcohol; and dissolving in water, acidulating with dilute hydrochloric acid, filtering, evaporating the filtrate to dryness and eliminating all free hydrochloric acid, then titrating with a standard alkaline solution.

Comments: The amount of citric acid present as citrated caffein can be ascertained approximately from the caffein found. The latter is the basis of the caffein citrate reported in this paper.

ACETANILID COMPOUND WITH CODEIN.

The term "codein" has come through lax usage to mean either the alkaloid, sulphate or phosphate. Strictly speaking, it means the alkaloid only and not any of its derivatives. The amount of sulphate or phosphate of this alkaloid present is usually small.

Caffein and acetanilid: Proceed as directed under acetanilid compound.

Codein: The acidulated solution in the separatory funnel from which the caffein and acetanilid have been extracted is rendered alkaline with potassium hydroxid. The liberated codein is extracted with successive portions of chloroform (15 cc. each), and the chloroformic solution filtered through a dry filter into a tared dish. The chloroform is then evaporated, the residue dried on a steam bath, cooled in a desiccator and weighed.

Comments: This gives anhydrous codein, $C_{14}H_{21}NO_3$. The purity of the codein may be determined by submitting it to the Pharmacopœial test prescribed for this drug. The amount and purity may also be checked by dissolving the codein in an excess of tenth normal sulphuric acid and titrating back the excess of acid with fiftieth normal potassium hydroxid, using methyl red as indicator. One cc. of tenth normal sulphuric acid is the equivalent of 0.031719 gram of crystallized codein, 0.0393 gram codein sulphate and 0.0433 gram codein phosphate.

If the insoluble matter should cause any difficulty, the solution may be filtered, the separatory funnel and filter washed, and all collected into another separatory funnel, then extracted as before directed.

The amount of codein found, if present in the form of sulphate or phosphate, may be checked by determining the amount of sulphate or phosphate present in the mixture, provided no other sulphate or phosphate is present.

ACETANILID COMPOUND WITH QUININ.

The quinin in this mixture is usually present in the form of sulphate. The compound may be analyzed as directed for acetanilid compound with codein.

Comments: This procedure gives anhydrous quinin. One cubic centimeter of tenth normal sulphuric acid is the equivalent of 0.037826 gram of U. S. P. quinin or 0.0436 gram quinin sulphate.

ACETANILID COMPOUND WITH SODIUM BROMID.

Caffein and acetanilid: Proceed as directed under acetanilid compound for these two chemicals except that the aqueous solution is rendered alkaline with either sodium or potassium hydroxid (free from chlorid) instead of acid.

Sodium bromid: Acidulate the solution remaining after removing the caffein and acetanilid with dilute nitric acid. Dilute to about 100 cc., filter, wash separatory funnel and filter paper with water and collect filtrate and wash in suitable beaker. The volume should finally amount to about 150 cc. Add tenth normal silver nitrate solution in excess to precipitate the bromin as silver bromid. Then add 1 cc. of ferric ammonium sulphate solution (10 percent) and titrate back the excess of silver nitrate with tenth normal solution of potassium thiocyanate. From the amount of tenth normal silver nitrate solution used the quantity of sodium bromid present in the mixture can readily be calculated.

Comments: In case the mixture is of such a character as to permit titration with silver nitrate without filtering, this part of the method may be omitted. One cubic centimeter of tenth normal silver nitrate is the equivalent of 0.010292 gram sodium bromid.

ACETANILID COMPOUND WITH SODIUM SALICYLATE.

Caffein and acetanilid: Proceed as directed under acetanilid compound with sodium bromid for determining caffein and acetanilid.

Sodium salicylate: Acidulate solution in separatory funnel, from which the caffein and acetanilid have been extracted, with dilute hydrochloric acid, remove the liberated salicylic acid with successive portions of chloroform. Transfer the chloroformic extract containing the salicylic acid into a tared beaker through a filter paper. Evaporate the chloroform at low temperature in a current of air, to avoid loss of any salicylic acid by volatilization. Finally, dry at 80° C., transfer to desiccator, cool, and weigh. From the amount of salicylic acid obtained by this operation the quantity of sodium salicylate in the mixture can be readily calculated.

Comments: The purity and the quantity of the salicylic acid can be determined by titrating the residue with tenth normal potassium hydroxid, using phenolphthalein as indicator. One cubic centimeter of tenth normal potassium hydroxid is the equivalent of 0.0138048 gram of salicylic acid or 0.0160 gram sodium salicylate.

Sodium bicarbonate: Proceed by method B under acetanilid compound.

Sodium bicarbonate and sodium salicylate: The total amounts of sodium bicarbonate and sodium salicylate in this way can be checked by incinerating a given weight of the material at a dull, red heat, dissolving the residue in water and titrating the sodium carbonate formed with standard sulphuric acid, using methyl orange as indicator. The total sodium carbonate so obtained should be equal to the amount of sodium carbonate that can be produced by incinerating the sodium bicarbonate and sodium salicylate.

One cubic centimeter of normal sulphuric acid is the equivalent of 0.084 gram sodium bicarbonate and 0.160 gram sodium salicylate.

ACETPHENETIDIN TABLETS.

Acetphenetidin: This chemical may be determined by Method A for estimating acetanilid in acetanilid tablets. The purity of the acetphenetidin is determined by the standard prescribed for this product by the Pharmacopœia. The melting temperature is from 134° to 135° C.

ACETPHENETIDIN AND CAFFEIN.

Acetphenetidin and caffein: Remove these chemicals from the mixture by the method for extracting acetanilid and caffein under acetanilid compound, transfer chloroformic solution to tared beaker, evaporate at room temperature in current of warm air, treat residue with 5 cc. of ether (which is rapidly dissipated at room temperature, heat to 80° C. for a short time, transfer to desiccator, cool and weigh. This gives the total acetphenetidin and caffein.

Caffein: Determine caffein by method for caffein under acetanilid compound.

Acetphenetidin: Deduct the amount of the caffein found from the combined weight of acetphenetidin and caffein, which gives acetphenetidin.

Comments: Acetphenetidin is not as readily hydrolyzed as acetanilid. For this reason especial care should be exercised to see that all particles of the acetphenetidin are dissolved in the acid solution by repeated rotation of the flask. If hydrolysis is incomplete the acetphenetidin will be extracted with the caffein and vitiate the results.

AMMONIUM CHLORID.

Ammonium chlorid, Method A: Dissolve a suitable amount in 50 cc. of water, acidulate with nitric acid, add an excess of tenth normal silver nitrate and titrate back with tenth normal potassium sulphocyanate, using 1 cc. of ferric ammonium sulphate solution (10 percent) as indicator.

Comments: For parallel reaction see ammonium bromid under acetanilid compound with sodium bromid. One cubic centimeter of tenth normal silver nitrate is the equivalent of 0.00535 gram of ammonium chlorid.

Ammonia gas (NH₃), Method B: Introduce about 1 gram of the material into a 500 cc. Kjeldahl flask, add 200 cc. of water and 15 cc. of a saturated solution of sodium hydroxid, and a few grains of granulated metallic zinc, No. 20, fine. Then distill the mixture until all of the ammonia gas has passed over.

Collect the distillate in a flask containing standard sulphuric acid. Sufficient liquid should be present in the flask receiving the distillate to cover the lower end of the condenser. Titrate back the excess of sulphuric acid, using cochineal as indicator. From the quantity of sulphuric acid consumed the ammonia gas can be readily calculated and from this the ammonium chlorid. The amount of ammonium chlorid obtained by this process should agree with the amount of ammonium chlorid obtained by the chlorid determination.

Comments: One cubic centimeter of normal sulphuric acid is the equivalent of 0.017034 gram of ammonia gas (NH_3) and 0.0535 of ammonium chlorid. In order to guard against any of the caustic alkali being carried over mechanically in the process of distillation, it will be necessary either to introduce a trap or incline the flask. This is a general method to be used for all ammonia compounds unless otherwise directed. The metallic zinc is added to minimize or prevent bumping.

Method C: Introduce 5 cc. of formaldehyde solution (37 percent) into a beaker containing 50 cc. of water, add a few drops of phenolphthalein solution and sufficient sodium hydroxid solution to render this mixture neutral, then add from $\frac{1}{2}$ to 1 gram of the material to be tested, bring the mixture to boiling and titrate acid formed with semi-normal sodium hydroxid solution.

One cubic centimeter of normal sodium hydroxid is the equivalent of 0.0535 gram of ammonium chlorid.

Talcum, etc.: Incinerate a convenient quantity in a suitable crucible.

AMMONIUM CHLORID AND CODEIN.

Ammonium Chlorid: Proceed as under ammonium chlorid.

Codein: Introduce about 1 gram accurately weighed into separatory funnel, dissolve in 25 cc. of water, render alkaline and finish operation as directed for codein under acetanilid compound with codein.

AMMONIUM SALICYLATE.

Salicylic acid: Introduce from $\frac{1}{2}$ to 1 gram, accurately weighed, into a separatory funnel, dissolve in about 25 cc. of water, acidulate with dilute sulphuric acid, and shake out with successive portions of 20 cc. of chloroform. Transfer chloroformic solution into tared beaker, through dry filter paper. Evaporate chloroform at slightly elevated temperature in a current of air. Finally dry the residue at 80°C ., cool in desiccator and weigh.

Comments: From the amount of salicylic acid obtained, calculate the ammonium salicylate. See salicylic acid under acetanilid compound with sodium salicylate. One cubic centimeter of tenth normal potassium hydroxid is the equivalent of 0.0155 gram of ammonium salicylate.

Talcum, etc.: See Ammonium chlorid.

AMMONIUM SALICYLATE COMPOUND.

This mixture usually contains ammonium salicylate, acetphenetidin, sodium bicarbonate and caffeine, together with the usual ingredients employed in the manufacture of tablets.

Acetphenetidin and caffeine: Extract as directed under acetanilid compound with sodium bromid, transfer chloroformic solution to tared beaker and finish by method under acetphenetidin and caffeine.

Ammonium salicylate, Method A: Follow directions for estimating sodium salicylate under acetanilid compound with sodium salicylate, substituting ammonium for sodium.

Method B, Ammonia gas (NH_3): Follow directions under ammonium chlorid.

AMMONIUM SALICYLATE COMPOUND WITH SALICIN.

Contains ammonium salicylate, acetphenetidin, caffeine, sodium bicarbonate, salicin, starch, etc. Exhaust about 2 grams, accurately weighed, with warm alcohol, transfer alcoholic extract to a 200 cc. tared beaker, through filter, evaporate in a current of warm air at room temperature or slightly above, heat at about $80^\circ C$. for one-half hour, cool and weigh. This gives the combined weights of ammonium salicylate, acetphenetidin, caffeine and salicin.

Caffeine and acetphenetidin: Transfer the residue into a separatory funnel with water and chloroform, using water first. The former should not exceed 50 cc. nor the latter 25 cc. Render the mixture alkaline and follow instructions under acetphenetidin and caffeine.

Ammonium salicylate: Acidulate solution from which caffeine and acetphenetidin have been removed with dilute hydrochloric acid and extract with chloroform. Proceed as directed under ammonium salicylate. This removes salicylic acid from the mixture.

Salicin: Transfer mixture from which salicylic acid has been removed to a 200 cc. beaker, wash separatory and filter paper with water, add washings to beaker, digest on steam bath until all chloroform has been dissipated, cool, dilute to about 175 cc., add 20 cc. of concentrated hydrochloric acid and finally make up to 200 cc. Mix thoroughly, transfer to 500 cc. flask, attach to reflux condenser and heat to boiling for two hours. Estimate the dextrose formed by method given in Bulletin No. 107 (Revised), Methods of Analysis, page 49.

or

Either formula may be used to calculate the salicin, from the dextrose formed, in that a given amount of salicin always produces the same quantity of dextrose.

ANALGESIC COMPOUND.

This mixture contains acetanilid, caffeine, sodium bicarbonate, codein sulphate, sodium salicylate, together with the usual excipients.

Caffeine and acetanilid: Place about 1 gram accurately weighed into separa-

tory funnel (A), add 25 cc. of chloroform, shake well, then add 25 cc. of water and enough dilute sulphuric acid to make acid. Agitate thoroughly, set aside to permit the chloroform to separate and clear. Transfer chloroform solution to another separatory funnel (B) through a dry filter. Repeat this operation with successive portions of chloroform until all the caffeine, acetanilid and salicylic acid are removed. Add 20 cc. of water and 5 cc. of normal sodium hydroxid solution, or sufficient to make distinctly alkaline, to the chloroformic solution in separatory funnel (B), agitate well, set aside to let chloroform separate and clear. Draw off chloroform solution into separatory funnel (C). Treat chloroformic solution in separatory (C) with several successive portions of slightly alkaline water until all of the sodium salicylate is removed. Collect all of the alkaline water in separatory funnel (B), wash with 20 cc. of chloroform which is to be transferred to separatory (C). Separatory (C) contains all of the caffeine and acetanilid in solution. Determine these drugs by method under acetanilid compound.

Salicylic acid: Render solution in separatory funnel (B) acid with dilute sulphuric acid, and proceed as directed under ammonium salicylate.

Codein: Render solution in separatory funnel (A) alkaline with potassium hydroxid solution, and follow directions for codein under acetanilid compound with codein.

ANODYNE COMPOUND.

The active ingredients are acetanilid, caffeine and sodium bicarbonate. Analyze as directed under acetanilid compound.

ANTIPYRIN TABLETS.

Proceed as directed for acetanilid, Method A, under acetanilid tablets.

Purity of antipyrin: The purity of the antipyrin can be determined by the standard prescribed by the Pharmacopœia. It should melt between 111° and 113° C.

ANTISEPTIC TABLETS.

The chief active agent in these tablets is corrosive sublimate. The term "antiseptic" is generally applied to mercuric chlorid mixed with citric acid, or ammonium chlorid or sodium chlorid. These chemicals increase the solubility of the mercurial compound and render it more useful as an antiseptic.

Mercuric Chlorid, Method A: In a 200 cc. beaker dissolve about $\frac{1}{2}$ gram, accurately weighed, in 100 cc. of water, acidulate with hydrochloric acid, heat to boiling, and precipitate with washed hydrogen sulphid gas. Transfer the precipitate to an ignited tared Gooch crucible, wash thoroughly with hot water and finally with alcohol; dissipate the alcohol from the Gooch crucible and wash the precipitate with repeated small portions of carbon bisulphid until all of the free sulphur is removed, dry at 100° C, cool and weigh as mercuric sulphid. From these data calculate the mercuric chlorid.

Comments: Methods B and C under Corrosive Sublimate tablets may also be applicable but they have not been tried.

Citric acid: Introduce 1 gram into a suitable beaker, add 25 cc. of water, an excess of neutral sodium chlorid, about 6 grams, dissolve and titrate directly with a standard potassium hydroxid solution, using phenolphthalein as indicator.

Comments: For determining ammonium chlorid or sodium chlorid see Cor-

rosive Sublimate with these ingredients. The added coloring matter frequently present in antiseptic tablets may interfere somewhat with the method. One cubic centimeter of tenth normal potassium hydroxid solution is the equivalent of 0.07003 gram of crystallized citric acid.

Arsenic trioxid: Treat a suitable amount of the powdered material with tenth normal sodium hydroxid solution to remove the arsenical compound, neutralize the solution with hydrochloric acid, add sodium bicarbonate, and treat immediately with tenth normal iodine solution.

One cubic centimeter of tenth normal iodine solution is the equivalent of 0.004948 gram of arsenic trioxid.

ASPIRIN TABLETS.

Follow directions for acetanilid (Method A) under acetanilid compound.

ATROPIN SULPHATE.

Atropin: Dissolve $\frac{1}{2}$ gram in water, render alkaline with ammonium hydroxid and extract with a mixture of ether, 1 part, chloroform, 2 parts. Transfer immiscible mixture containing the atropin to a tared beaker, evaporate at room temperature in a current of warm air. Finally heat at 100° C. for a few minutes, transfer to desiccator, cool and weigh.

Comments: Atropin sulphate tablets should be freely soluble in water. The lubricant usually employed for this form of medication is boric acid.

BISMUTH SUBNITRATE.

Bismuth oxid, Method A: Ignite in a small, fused silica evaporating dish 2 grams accurately weighed of bismuth subnitrate at a dull, red temperature until all nitrous vapors cease to be evolved and all organic matter is destroyed. Cool, add a few drops of nitric acid to convert any metallic bismuth into nitrate, heat gently to evaporate excess of acid and ignite as before. Transfer evaporating dish to desiccator, cool and weigh. Deduct weight of talcum (below) which leaves amount of bismuth oxid.

Bismuth oxid, Method B: By determining the nitrogen present the amount of bismuth subnitrate can be approximately estimated. Methods for determining nitrogen in nitrate bearing substances will be found in Methods of Analysis, Bulletin 107 (Revised), pages 7 to 9, inclusive.

Talcum, etc.: Weigh 3 grams of powdered material into a suitable beaker, add 25 cc. of 20 percent nitric acid, mix thoroughly, warm to 40° C., set aside for about one hour, and during the interim agitate from time to time, then transfer to a tared previously heated Gooch crucible provided with a nitric acid treated mat of asbestos, using a little 20 percent nitric acid. Wash residue with a little nitric acid of same strength, then with dilute (10 percent) nitric acid and finish with water. Dry residue, ignite to a white or nearly white ash, cool and weigh.

Comments: Bismuth subnitrate varies somewhat in composition. It should, however, yield not less than 80 percent of pure bismuth oxid.

BISMUTH SUBNITRATE AND CALOMEL.

Bismuth subnitrate: Determine this chemical by a method given under bismuth subnitrate.

Calomel: Introduce about 2 grams accurately weighed into a 200 cc. flask, add 50 cc. of water and 25 cc. of approximately normal potassium hydroxid. Attach flask to reflux condenser and heat for about one-half hour, filter, wash residue with water and collect filtrate and washings in beaker, acidulate contents with nitric acid, add an excess of silver nitrate to precipitate the chlorid, titrate back excess of silver nitrate with tenth normal solution of potassium sulphocyanate, using about 1 cc. of ferric ammonium sulphate, 10 percent as indicator. One cubic centimeter of tenth normal silver nitrate is the equivalent of 0.023606 gram of calomel.

Comments: If there is an excessive amount of starch present the method becomes very difficult, if not impossible, of operation.

CAFFEIN ALKALOID.

Caffein: Proceed as directed for acetanilid (Method A) under acetanilid tablets.

After evaporating the chloroform solution to apparent dryness, add 5 cc. ether, evaporate carefully, finally dry at 80° C. for one-half hour, cool in desiccator and weigh.

CAFFEIN CITRATED.

Caffein: Proceed as directed under acetanilid compound for estimating caffein, except that chloroform solution is carefully evaporated to dryness and the procedure concluded as under caffein alkaloid.

Citric acid: Introduce about 2 grams, accurately weighed, into a beaker, dissolve in 25 cc. of water, and determine the amount of citric acid by means of tenth normal potassium hydroxid solution, using phenolphthalein as indicator. See citric acid antiseptic tablets.

CALOMEL AND SODIUM BICARBONATE.

Calomel, Method A: Introduce into a beaker about 1 gram, accurately weighed, disintegrate with about 50 cc. of water, add 5 grams of potassium iodid, agitate the mixture for a short time, then add an excess of standard tenth normal iodine solution. Allow the solution to stand for about 15 minutes, then determine the excess of iodine with a standard tenth normal solution of sodium thiosulphate, using starch paste as indicator.

Comments: In order to insure against possible error, run a control, using the same amount of potassium iodid and iodine solution as in the procedure above. The iodine solution and the potassium iodid may be added in reverse order and it is claimed by some with better results.

One cubic centimeter of tenth normal iodine solution is the equivalent of 0.023606 gram of calomel.

Method B: Introduce into a 200 cc. beaker about 1 gram, accurately weighed, of the mixture, treat with warm water (not above 60° C.) and assist in disin-

tegrating the tablets by means of a stirring rod, allow the mixture to stand for about one-half hour, then filter and collect the calomel on a tared, previously ignited, porcelain Gooch crucible, provided with an asbestos mat, wash with water and finally with alcohol, then dry at 100° C., cool in a desiccator and weigh. Heat the Gooch crucible in a Bunsen flame sufficiently to completely volatilize the calomel. The difference between the two weights represents the calomel.

Method C: Introduce about $\frac{1}{2}$ gram, accurately weighed, into a 100 cc. beaker, add 20 cc. of water and about 10 cc. of normal sodium hydroxid solution, transfer to steam bath and heat for about one hour. This procedure will disintegrate the calomel, forming insoluble mercury compounds, chiefly mercurous oxid, and sodium chlorid. After the reaction is complete dilute to 50 cc., filter through a Gooch crucible, and wash thoroughly with hot water. Acidulate the filtrate with nitric acid, add standard tenth normal solution of silver nitrate to excess and 1 cc. of ferric ammonium sulphate solution, then titrate back the excess of silver nitrate, with tenth normal potassium thiocyanate.

Comments: If desired, the silver chlorid may be collected in a Gooch crucible and determined in the usual way. From the data above the amount of calomel can be readily calculated. If the mixture contains starch or a gummy substance this method will not work satisfactorily.

One cubic centimeter of tenth normal silver nitrate is the equivalent of 0.023606 gram of mercurous chlorid.

Sodium bicarbonate: Titrate a given weight with normal sulphuric acid, using methyl orange as indicator if no disturbing agents are present. One cubic centimeter of tenth normal sulphuric acid is the equivalent of 0.084 gram of sodium bicarbonate.

CALOMEL AND LACTOSE.

Calomel: Proceed as directed under calomel and sodium bicarbonate.

Lactose: Introduce about 1 gram, accurately weighed, into a 100 cc. glass-stoppered flask or cylinder, add about 50 cc. of water, agitate thoroughly to disintegrate, and finally make up to 100 cc. Mix thoroughly and filter; reject the first 20 cc. of the filtrate. Proceed from this point as directed on pages 241-2 of Methods of Analysis, Bureau of Chemistry, Bulletin No. 107 (revised).

CINCHONIDIN.

Cinchonidin: Introduce 1 gram of the finely powdered material into a separatory funnel, add 50 cc. of water, and acidulate with dilute sulphuric acid, add 25 cc. of chloroform, render alkaline with sodium hydroxid, agitate thoroughly, set aside for the chloroform to separate and then proceed as directed for codein under "Acetanilid Compound with Codein."

Comments: If the insoluble matter interferes with the process, filter the acidulated solution, then render alkaline, add chloroform and continue as above. The purity of the cinchonidin and many other alkaloids can be determined by dissolving in a little neutral alcohol, adding a slight excess of tenth normal sul-

phuric acid and titrating back excess of acid by means of fiftieth normal potassium hydroxid, using methyl red as indicator. Tenth normal factor for cinchonidin is 0.0294196.

CINCHONIDIN SULPHATE.

Follow directions under cinchonidin.

COCAIN AND COCAIN HYDROCHLORID.

Follow directions under cinchonidin. Tenth normal factor for cocain is 0.0303178; for cocain hydrochlorid 0.03396.

CODEIN AND CODEIN SULPHATE.

Follow directions under cinchonidin. Tenth normal factor for codein, 0.031719; for codein sulphate, 0.0393.

CORROSIVE SUBLIMATE TABLETS.

This chemical is generally mixed with such ingredients as sodium chlorid, ammonium chlorid, and citric acid, but it is also put in tablet form by means of lactose. In the latter case the term "tablet triturate" is usually applied. Mercuric chlorid tablets are frequently colored artificially.

Mercuric chlorid: Estimate by Method A under antiseptic tablets, and as follows:

Method B: Introduce 1 gram accurately weighed into a 250 cc. flask, dissolve in 25 cc. water, add $2\frac{1}{2}$ grams of potassium iodid (dissolved in 5 cc. of water), 30 cc. of normal caustic alkali or sufficient to make alkaline and 3 cc. of a 37 percent formaldehyde solution, mix thoroughly and set aside for 10 minutes with occasional shaking, then add 10 cc. or sufficient to make acid, 36 percent acetic acid, diluted with an equal volume of water, mix well, finally add 50 cc. of tenth normal iodine solution, stopper flask and shake vigorously for two minutes, then occasionally until the mercury is dissolved. Estimate excess of iodine with tenth normal sodium thiosulphate solution, using starch as indicator. Deduct the excess of iodine from the total amount of iodine used which gives the amount of iodine combined with the mercury.

Comments: In an alkaline medium formaldehyde reduces the mercury in the corrosive sublimate to the metallic state. The following equation shows the reaction between the metallic mercury and iodine:

Each cubic centimeter of tenth normal iodine solution is the equivalent of 0.01385 of mercuric chlorid.

Method C: Dissolve about 1 gram of the substance, equivalent to about $\frac{1}{2}$ gram of mercuric chlorid, accurately weighed, in 75 cc. of water and render neutral, if not already so, to methyl orange, litmus or some other suitable indicator, add 10 cc. of 2 percent hydrocyanic acid solution, also made neutral to the indicator to be used. Estimate the amount of hydrochloric acid liberated by titrating with fifth normal sodium hydroxid solution.

Comments: The method depends upon the formation of an undissociated molecule of mercuric cyanid and the liberation of hydrochloric acid. The acidity of the hydrocyanic acid solution to the particular indicator to be used can be

determined and subtracted from subsequent operations instead of making this determination for each titration. The indicator to be used depends on the nature of the coloring matter present, if any.

Reactions: $\text{HgCl}_2 + 2\text{HCN} = \text{Hg}(\text{CN})_2 + 2\text{HCl}$ or

Each cubic centimeter of fifth normal sodium hydroxid is the equivalent of 0.02715 gram of mercuric chlorid.

CORROSIVE SUBLIMATE AND AMMONIUM CHLORID.

Mercuric chlorid: Proceed as directed for determining this chemical by methods under antiseptic tablets and corrosive sublimate tablets.

Ammonia Gas (NH_3): Place about 1 gram accurately weighed into a 500 cc. Kjeldahl flask, dissolve in 200 cc. water, add 25 cc. of potassium sulphid solution (40 grams of commercial potassium sulphid dissolved in 1 liter of water)¹ or sufficient to precipitate all of the mercury. Render alkaline with sodium hydroxid and proceed from this point as directed by Method B under ammonium chlorid.

CORROSIVE SUBLIMATE AND SODIUM CHLORID.

Mercuric chlorid: Proceed by Method, A, B or C under corrosive sublimate tablets.

Method D: Into a tared porcelain evaporating dish weigh about 1 gram of the substance, previously dried at 100° C., heat in a muffle furnace at a dull, red temperature until all of the corrosive sublimate is volatilized, transfer dish to desiccator, cool and weigh. The loss represents mercuric chlorid and organic coloring matter, if present.

Sodium Chlorid, Method A: The residue left in the evaporating dish by Method D above represents the sodium chlorid.

Method B: Dissolve the residue left by Method D above in 50 cc. of water, acidulate with nitric acid and add an excess of tenth normal silver nitrate solution. Titrate back excess of silver nitrate with potassium sulphocyanid, using 1 cc. of 10 percent ferric ammonium sulphate solution as indicator.

Comments: If the amount of sodium chlorid should require too much silver nitrate solution, the residue can be dissolved in a suitable volume of water and an aliquot taken for the determination.

One cubic centimeter of tenth normal silver nitrate solution is the equivalent of 0.005846 gram of sodium chlorid.

HEROIN HYDROCHLORID.

Proceed as directed under cinchonidin.

HEROIN AND PHENACETIN.

Phenacetin: Introduce from 1/2 to 1 gram of the material into a separatory funnel, add 25 cc. of chloroform, agitate well, then add 25 cc. of water, and sufficient dilute sulphuric acid to acidulate, repeatedly agitate so as to bring about complete solution of the water-soluble material, then set aside to permit the chloroform to clear and separate. Transfer the chloroformic solution to tared

¹See Methods of Analysis, Bull. 107 (revised), p. 6.

beaker. Repeat the operation until all the phenacetin is removed from the mixture. Finish by Method A under acetanilid tablets.

Heroin: Render the solution from which the phenacetin has been removed alkaline with potassium hydroxid and proceed as directed under cinchonidin. One cubic centimeter of tenth normal sulphuric acid is the equivalent of 0.03692 gram of diacetyl morphin or 0.040566 gram diacetyl morphin hydrochlorid.

HEXAMETHYLENAMIN.

This chemical is usually compressed without the addition of any foreign material, and it is therefore generally necessary only to accurately weigh the tablets in order to determine whether or not they are of proper weight.

It is desirable, however, to examine the product by the Pharmacopœial test. If it should be found that foreign material is present, such as talcum, starch, etc., the powdered material can readily be extracted with chloroform, the chloroformic extract collected in a tared beaker, evaporated, dried, cooled and weighed.

Nitrogen: By determining the percent of nitrogen the amount of hexamethylenamin and its purity can readily be ascertained. The nitrogen may be estimated by Kjeldahl or Gunning method, in Methods of Analysis, Bulletin of Bureau of Chemistry No. 107 (revised), pages 6 and 7, respectively. Hexamethylenamin contains 39.99 percent of nitrogen.

MIGRAIN TABLETS.

Under this name various mixtures are met with. A common one consists of acetanilid, caffein and sodium bicarbonate. Analyze by methods prescribed under acetanilid compound.

A second mixture encountered consists of acetanilid, caffein, sodium bicarbonate and sodium salicylate. This combination may be analyzed by procedure outlined under acetanilid compound with sodium salicylate.

MORPHIN SULPHATE.

This chemical is usually compressed with lactose. Boric acid is commonly used as lubricant. The amount of morphin may be determined either directly or indirectly as follows:

Morphin, Method A: Dissolve from $\frac{1}{2}$ to 1 gram in 25 cc. of water in a suitable vessel, render alkaline with ammonium hydroxid, agitate well and allow to stand one-half hour, transfer to funnel with a small plug of cotton in throat. The precipitated morphin will be collected on the cotton. Wash the morphin sufficiently with cool water to remove all of the ammonia, then transfer the morphin and cotton to a porcelain evaporating dish, using from 25 to 50 cc. of alcohol (neutral), depending on the amount of morphin, add a slight excess of tenth normal sulphuric acid to convert the morphin into morphin sulphate, allow to stand a short time, then titrate back excess of acid with fiftieth normal potassium hydroxid, using methyl red as indicator. One cubic centimeter of tenth normal sulphuric acid is the equivalent of 0.03032 gram of morphin, or 0.0379 gram of morphin sulphate.

Method B: Estimate the amount of sulphate present in a definite quantity of morphin tablets by precipitating with barium chlorid in the usual manner. From

the amount of barium sulphate obtained, the amount of morphin sulphate can be readily calculated.

Method C: Determine nitrogen by Kjeldahl or Kjeldahl-Gunning methods, pages 5 and 7, respectively, Methods of Analysis, Bulletin No. 107. The nitrogen may also be estimated by Kjeldahl-Gunning-Arnold method. (U. S. Department of Agriculture, Bureau of Chemistry Circular 108, p. 15, 1912.)

Comments: The latter process is shorter than either of the other two. It is identical with the official Kjeldahl method except that 10 grams of crystallized potassium sulphate are added as in the Gunning method, omitting the potassium permanganate.

Lactose: Proceed as directed for this carbohydrate under calomel and lactose.

NITROGLYCERIN TABLETS.

Preparation of the sample: Crush 25 tablets under 10 cc. of ether. A 25 cc. cylindrical graduate makes a convenient container and a stout glass rod is used to crush the tablets. Rinse the rod with a little ether, allow the insoluble material to settle, and decant the solution into a 50 cc. graduated flask. No special care need be taken to prevent a little insoluble material from going into the flask. Wash the residue repeatedly with 5 cc. portions of ether and decant the washings into the flask until it has been filled to the mark. Insert stopper and mix well.

Nitrate Method: Place 20 cc. of the ethereal solution in a carefully dried and tared 50 cc. beaker. (A second aliquot of 10 cc. may be used as a check.) Evaporate the solvent in a vacuum desiccator charged with sulphuric acid. Apply the vacuum gradually, to prevent ebullition. Leave the beaker in the vacuum 30 minutes after the ether has evaporated. Weigh and calculate the ether extract per tablet. Treat the residue with 2 cc. phenoldisulphonic acid reagent, rotating the beaker in such a way that the reagent comes in contact with the entire inner surface. After 10 minutes add water and wash into a 100 cc. flask. (If a check analysis, as suggested, was made, wash this into a 50 cc. flask. Dilute to the mark and place 10 cc., representing 1 tablet, in a 100 cc. flask, add about 50 cc. water and a few drops more potassium hydroxid solution (20 percent) than is required to neutralize the acid. (Do not use sodium hydroxid.) Dilute to the mark and compare the color with that produced by a standard nitrate solution similarly treated. Use any convenient colorimeter or Nessler tubes.

Reagents and standards: Phenoldisulphonic acid reagent.—Dissolve 25 grams of pure white phenol in 150 cc. of concentrated sulphuric acid, add 75 cc. of fuming sulphuric acid (13 percent SO_3), stir well, and heat for two hours at about 100 degrees.

Standard Solution.—Dissolve 0.7217 gram potassium nitrate in 1 liter of water. Evaporate 10 cc. of this solution just to dryness on the steam bath. Cool and treat the residue with 2 cc. phenoldisulphonic acid reagent, observing the precautions noted above and using a glass rod if necessary to aid the solution of the residue. After 5 or 10 minutes dilute to 250 cc. Each cubic centimeter of this solution contains 0.004 milligram of nitrogen. Add an excess of potassium hydroxid solution to an aliquot of this solution and dilute to 100 cc. It is advisable to prepare a standard of approximately the same color as the unknown. Nitro-glycerin is 5.4 times nitrate nitrogen.

Reactions:

Nitrite or modified Hay method: Place 5 cc. of the ethereal solution in a 50 cc. beaker, dilute with 5 or 10 cc. alcohol and add about 5 cc. of ½ percent. alcoholic potassium hydroxid. Cover with a watch glass and allow to stand 10 minutes. Place on steam bath, allow to boil, remove the watch glass, and when most of the liquid is evaporated add about 25 cc. water and leave on steam bath until about half the liquid has evaporated or until the odor of alcohol can no longer be detected. Cool and dilute to 250 cc. Each cubic centimeter of this solution represents 0.01 of a tablet. Introduce an aliquot representing 0.02 to 0.04 milligram of nitroglycerin into a 100 cc. graduated flask, dilute with sufficient water to make the volume 90 to 95 cc., add 1 drop concentrated hydrochloric acid, then 2 cc. sulphanilic acid solution and 2 cc. naphthylamine hydrochlorid solution. Complete the volume with water. Prepare at the same time and in the same way standards containing known amounts of sodium nitrite. Stopper the flasks and mix well. Compare the colors after 30 minutes. Nitroglycerin is calculated by multiplying the nitrogen found by 8.

Reagents and standards: Sulphanilic acid solution.—Dissolve 1 gram in 100 cc. hot water.

Naphthylamine hydrochlorid solution.—Under a hood boil 0.5 gram of the salt with 100 cc. water for 10 minutes, keeping the volume constant. Filter and keep in a glass stoppered bottle.

Standard solution of sodium nitrite.—To a cold solution of about 2 grams of sodium or potassium nitrite in 50 cc. of water, add a solution of silver nitrate as long as a precipitate appears. Decant the liquid and thoroughly wash the precipitate with cold water. Dissolve in boiling water. On cooling the silver nitrite is precipitated. Dry the crystals in the dark at the ordinary temperature (preferably in a vacuum). Weigh out 220 milligrams of the dry silver nitrite, dissolve in hot water and decompose with a slight excess of sodium chlorid. When the solution becomes clear, dilute to 1 liter. Dilute 5 cc. of this solution to 1 liter. This second dilution is the standard to be used. It contains 0.0001 milligram of nitrite nitrogen per cubic centimeter.

Essential reactions:

Sulphanilic acid. Paradiazobenzenesulphonic acid.

Alpha Azoalphamidonaphthalene-
Naphthylamine. parazobenzenesulphonic acid.

Comments: Only nitrite-free water should be used in the estimation by this method.

NUX VOMICA TABLETS.

Total alkaloids: Introduce 5 grams of the material into a 200 cc. graduated cylinder, add 100 cc. of chloroform-ether mixture (1-4 by volume), agitate well and repeatedly for one-half hour, add 5 cc. of ammonia water, or sufficient to render alkaline, agitate repeatedly for 1 hour, then make up to 150 cc., agitate well, set aside for the insoluble matter to settle and the chloroform-ether mixture to clear, then decant or pipette off an aliquot part (for example, 100 cc.) and transfer to separatory funnel. Acidulate chloroform-ether solution with dilute sulphuric acid and add enough water to make about 25 cc. aqueous solution, agitate well, allow to separate and draw off the watery portion into another separatory. Repeat this operation two or three times with about 20 cc. of water and collect in separatory funnel. Render the acid solution in second separatory funnel alkaline with ammonia water, extract with three successive portions of 20 cc. of chloroform, collect chloroformic solution in another separatory, wash with 25 cc. of water, transfer the chloroform into tared beaker, evaporate on steam bath at low temperature. Rinse separatory funnel with a small portion of chloroform and transfer to beaker. When chloroform is dissipated add about 5 cc. of ether, evaporate and dry at 100° C. for one-half hour, cool and weigh.

Strychnin: Destroy brucin in dried residue by adding 6 cc. of 35 percent nitric acid, mixing well and allowing the mixture to stand at ordinary temperature for 10 minutes.

Take up residue with water and transfer to separatory funnel with several small portions of water, render alkaline with ammonia water, and proceed as directed for total alkaloids.

Comments: The amount of strychnin and its purity may now be determined by taking the alkaloid up in a little (neutral) alcohol, adding a slight excess of tenth normal sulphuric acid and titrating back excess of acid with fiftieth normal potassium hydroxid, using methyl red as indicator.

One cubic centimeter of tenth normal sulphuric acid is the equivalent of 0.0334 gram of strychnin.

Brucin: Determine by subtracting strychnin from total alkaloids.

PHENACETIN TABLETS.

Analyze by methods under acetanilid tablets. Determine phenacetin by Method A.

PHENOLPHTHALEIN.

Determine by Method A under acetanilid tablets, using alcohol, however, in place of chloroform.

Comments: This chemical is now found in all forms of mixtures. A little organic acid is sometimes used to prevent the tablets from turning reddish.

POTASSIUM BICARBONATE.

Potassium bicarbonate is generally compressed without any excipient; in such cases titration may be made directly; otherwise, extract a suitable quantity of the powder with water, filter, wash and titrate the aqueous solution with standard sulphuric acid, using methyl orange as indicator.

One cubic centimeter tenth normal acid is the equivalent of 0.01001 gram of potassium bicarbonate.

POTASSIUM IODID.

Titrate direct, or, when foreign matter is present, extract a convenient quantity with water, wash residue, collect filtrate and washings in beaker, acidulate with nitric acid, add an excess of silver nitrate to precipitate the iodine, then titrate back with a tenth normal solution of potassium sulphocyanate, using about 1 cc. ferric ammonium sulphate, 10 percent solution, as indicator.

Reaction: $KI + AgNO_3 = AgI + KNO_3$.

One cubic centimeter of silver nitrate is the equivalent of 0.016602 gram of potassium iodide.

POTASSIUM PERMANGANATE.

Extract a suitable quantity with water, acidulate with sulphuric acid, warm to about 60° C., and titrate with a tenth normal oxalic acid solution.

Reactions: $2KMnO_4 + 5H_2C_2O_4 + 3H_2SO_4 = K_2SO_4 + 2MnSO_4 + 10CO_2 + 8H_2O$.

One cubic centimeter of tenth normal oxalic acid is the equivalent of 0.00316 gram of potassium permanganate.

QUININ BISULPHATE AND QUININ SULPHATE.

Proceed as directed under cinchonidine.

One cubic centimeter of tenth normal sulphuric acid is the equivalent of 0.0378 gram of crystalline quinine, 0.0436 gram of quinine sulphate and 0.0548 gram of quinine bisulphate.

RHEUMATIC TABLETS.

One mixture was found to consist of sodium salicylate, and sodium bicarbonate, together with excipients.

Salicylic acid: Proceed as directed for salicylic acid under ammonium salicylate.

Sodium bicarbonate, talcum, etc.: Proceed as directed under acetanilide compound.

A second mixture was found to contain sodium salicylate, sodium bicarbonate and codeine sulphate.

Salicylic acid: Proceed as directed for determining salicylic acid under ammonium salicylate.

Codeine sulphate: Codeine sulphate will be left in the solution from which the salicylic acid has been extracted. This can be removed by rendering the solution alkaline, thus liberating the codeine which may now be extracted from the mixture by chloroform. The remainder of the procedure is given under Acetanilide Compound with Codeine.

SALICIN TABLETS.

Exhaust a suitable quantity of the powdered material by Method A, under acetanilide tablets, substituting, however, alcohol for chloroform.

SALOL TABLETS.

This article may be analyzed by methods under acetanilide tablets. Salol is determined by Method A, using ether in place of chloroform. Considerable care must be exercised in dissipating the solvent so that none of the salol is lost. The best course to follow is to permit the ether to evaporate at room temperature in a current of warmed air, then introduce the beaker into a vacuum desiccator and allow it to remain for 24 hours before weighing.

SALOPHEN TABLETS.

Determine by Method A under acetanilid tablets.

SANTONIN AND CALOMEL.

Santonin: Determine by Method A under acetanilid tablets.

Calomel: Determine this chemical in residue left after extracting the santonin with chloroform by Method A given under calomel and sodium bicarbonate.

SODIUM SALICYLATE TABLETS.

Salicylic acid: Proceed as directed under ammonium salicylate for determining salicylic acid.

Sodium salicylate: Ignite a given weight of the material, extract the residue with water and titrate with tenth normal sulphuric acid, using methyl orange as indicator.

One cubic centimeter of tenth normal sulphuric acid is the equivalent of 0.0160 gram of sodium salicylate.

SODIUM BICARBONATE.

Determine by method given under potassium bicarbonate. The normal factor for sodium bicarbonate is 0.084.

SODIUM BROMID.

Determine by method given under potassium iodid. Tenth normal factor for sodium bromid is 0.010292.

STRONTIUM BROMID.

Determine by method given under potassium iodid. The tenth normal factor for strontium bromid is 0.01778.

STRYCHNIN SULPHATE.

Introduce about 1 gram of the powdered tablets into separatory funnel, dissolve in 25 cc. of water rendered alkaline and remove the strychnin with three or more successive portions of chloroform. The chloroform solutions are collected in a tared beaker and evaporated to dryness. The residue is allowed to cool, 5 cc. of ether added, the ether dissipated and the residue dried at 100° C. for 15 minutes.

Comments: Care should be exercised in drying so that no loss will occur by decrepitation of the strychnin. The purity and amount of strychnin present may be determined by dissolving the residue in neutral alcohol, adding an excess of tenth normal sulphuric acid, and titrating back excess of acid with fiftieth normal potassium hydroxid, using methyl red as indicator. One cubic centimeter of tenth normal sulphuric acid is the equivalent of 0.0334 gram of strychnin and 0.0428 gram strychnin sulphate.

SALOPHEN.

Exhaust from $\frac{1}{2}$ to 1 gram of the powdered material with alcohol, as directed under acetanilid tablets, transfer alcoholic filtrate into tared beaker, evaporate the alcohol and heat the residue for 15 minutes at 100° C., transfer beaker to desiccator, cool and weigh.

Comments: The purity of salophen can be determined by ascertaining its melting temperature which varies from 187° to 188° C.

TRIONAL.

Proceed as directed under salophen.

Comments: The melting point of trional is 76° C.

VERONAL.

Proceed as directed under salophen, using, however, acetone as solvent.

Comment: Melting point, 188° C.

ZINC PHENOLSULPHONATE.

Zinc oxid: Exhaust from ½ to 1 gram of powdered material with alcohol, as directed under acetanilid tablets, collect filtrate in tared evaporating dish, dissipate the alcohol, incinerate the residue in a muffle at a dull, red heat until a white or nearly white residue is left. Cool dish in desiccator and weigh residue as zinc oxid.

Comments: Uneffloresced zinc phenolsulphonate leaves 14.6 percent of its weight as zinc oxid on ignition.

Reaction: $\text{Zn}(\text{C}_6\text{H}_4(\text{OH})\text{SO}_3) + 14\text{O}_2 = \text{ZnO} + 12\text{CO}_2 + 2\text{SO}_3 + 5\text{H}_2\text{O}$.

Residue insoluble in alcohol: See residue insoluble in chloroform under acetanilid tablets. By deducting the amount of residue so obtained from the total amount of material originally taken the quantity of alcohol-soluble material (zinc phenolsulphocarbolate, chiefly), is obtained.

THE COST OF RODENTS.

Rats, mice, flies, mosquitoes, and the various form of body parasites have always been held in contempt and disgust, and always and everywhere have been regarded as vermin. Growing knowledge of the important role played by these lower forms of animal life in the transmission of disease is ample justification for this feeling. They are exceedingly expensive.

The Journal of the American Medical Association comments on a recent article in The Farm and Fireside, which discusses the amount of damage done in this country by rats, and estimates that there are in the United States at least 300,000,000 of these animals, alike destructive to property and dangerous to health. Rats are said to destroy \$100,000,000 worth of grain every year in this country, or enough to feed one hen for every man, woman and child in the nation. The annual cost of rats to the nation is estimated at \$360,000,000.

In addition, the rat population of the country forms a fertile field for the dissemination of bubonic plague, which only needs a starting point in any of our seaports to spread throughout the country and cause the loss of thousands of lives.

In the same issue of The Farm and Fireside, but in a different department, appears an article on the cattle tick, in which it is estimated that the difference between the market value of an animal free from this parasite and one infested with it is about \$8 a cow, and that the cattle tick is today costing the stockmen of the country \$1,000,000,000 each decade, or \$100,000,000 each year.

The discovery and development of bacteriology showed that man had been carrying on for centuries an unconscious struggle with the lower forms of vegetable life. Recent additions to knowledge of the habits and characteristics of vermin show that an equally relentless struggle has been going on between man and the lower forms of animal life.

Contributed and Selected

UNITED STATES PHARMACOPŒIA.

NINTH REVISION.

ABSTRACT OF PROPOSED CHANGES WITH NEW STANDARDS AND DESCRIPTIONS.

Copyright, 1914, by the Board of Trustees of the United States Pharmacopœial Convention.*
All Rights Reserved

PART V—FIRST PROOF.

A fifth installment of the Abstract of proposed new descriptions and standards and of changes in descriptions and standards is herewith submitted.

This Abstract embraces most of the Biological Products and Volatile Oils. Where no reference is made to rubrics, tests or assays, it is understood that the material facts remain the same as in the *United States Pharmacopœia*, Eighth Revision.

Other Abstracts will be submitted later. Comments should be sent to the Chairman of the Revision Committee, Joseph P. Remington, Longport, New Jersey, before September 1, 1914.

BIOLOGICAL PRODUCTS.

Glandulæ Suprarenales Siccæ.—The suprarenal glands of such animals as are used for food by man, cleaned, dried, freed from fat, and powdered, and yielding not less than 0.4 percent. nor more than 0.6 percent. of epinephrine. Added requirement: Not more than 7 percent. of moisture. *Assay*: Add 0.005 Gm. of finely powdered manganese dioxide and 10 Cc. of distilled water to 0.010 Gm. of Desiccated Suprarenal Glands; thoroughly shake the mixture several times during one hour and filter. Compare the color of the filtrate in a test-tube or in any convenient manner, with the color of standard solutions made as follows: Mix 1.85 Cc. of cobaltous chloride T. S. with 0.95 Cc. of gold chloride T. S. and 7.2 Cc. of distilled water; the color corresponds to 0.2 percent. of epinephrine in the filtrate obtained above; 2.95 Cc. of cobaltous chloride T. S. with 1.25 Cc. of gold chloride T. S. and 5.8 Cc. of distilled water corresponds in color to 0.4 percent. of epinephrine; 4.05 Cc. of cobaltous chloride T. S. with 1.35 Cc. of gold chloride T. S. and 4.6 Cc. of distilled water corresponds in color to 0.6 percent. of epinephrine; 5.15 Cc. of cobaltous chloride T. S. with 1.55 Cc. of gold chloride T. S. and 3 Cc. of distilled water corresponds in color to 0.8 percent. of epinephrine. The percentages of epinephrine indicated by the above color standards are based upon the maceration of 0.010 Gm. of the Desiccated Suprarenal Glands in 10 Cc. of distilled water as directed above and filtering. In samples containing more than 0.8 percent. of epinephrine, 0.005 Gm. of the Desiccated Suprarenal

*Permission to reprint for purposes of comment can be had on application to the Chairman of the Board of Trustees, J. H. Beal, Scio, Ohio.

Glands may be taken, in which case the percentage stated above, as indicated by the color standards, should be doubled. The standard color solutions keep unchanged indefinitely if sealed in test-tubes. The former test with ferric chloride T. S. is omitted.

Note.—The test solutions required above are made as follows:

Cobaltous Chloride T. S.—Two Gm. of Cobaltous Chloride dissolved with the aid of 1 Cc. of hydrochloric acid in sufficient distilled water to measure 100 Cc.

Gold Chloride T. S.—An aqueous solution of Gold Chloride containing 0.1 Gm. of gold in each 100 Cc. of solution, determined by analysis.

Glandulae Thyroideae Siccæ.—The Thyroid Glands of such animals as are used for food by man, freed from connective tissue and fat, dried and powdered and yielding not less than 0.17 percent. nor more than 0.23 percent. of iodine in thyroid combination. Iodine in inorganic or any other form of combination than that peculiar to the thyroid must be absent. Added requirement: Not more than 6 percent. of moisture. Ash changed from 6 percent. to 5 percent. Assay for iodine replacing former test for iodine compounds: Mix 1 Gm. of Desiccated Thyroid Glands in a nickel crucible of about 125 Cc. capacity, with 15 Gm. of a mixture composed of 138 parts by weight of anhydrous potassium carbonate, 106 parts of anhydrous sodium carbonate and 75 parts of potassium nitrate. Spread an additional 5 Gm. of this fusion mixture evenly over the surface. Heat the crucible over a Bunsen flame until no further carbonization is observed, cool it and dissolve the residue in about 150 Cc. of distilled water, warming to hasten solution. Transfer this solution to an Erlenmeyer flask of about 500 Cc. capacity, and add approximately 50 Cc. of a fresh solution of chlorinated soda. Now treat the mixture with enough phosphoric acid, diluted with an equal volume of distilled water, to produce an appreciable yellow tint of free chlorine, then add 10 Cc. more of the phosphoric acid diluted with an equal volume of distilled water and boil the contents of the flask for one-half hour or until the volume has been reduced to about 150 Cc. Cool the liquid, add 10 Cc. of an aqueous solution of potassium iodide (1 in 100) and titrate the liberated iodine with two-hundredth normal sodium thiosulphate V. S., starch paste being used as indicator just before the end of the reaction.

Serum Antidiphthericum.—Added description: "With sometimes a slight granular sediment." Definition and description otherwise as in U. S. P. VIII. The serum must come from healthy animals; must be sterile; must be free from toxin or bacterial products; and must not contain an excessive amount of preservative (0.5 percent. phenol, or 0.4 percent. cresol when such are used); and the total solids should not exceed 20 percent. Serum of a lower potency than 250 units per cubic centimeter is not to be sold. Only Serums may be sold as have been prepared and propagated in establishments licensed by the Secretary of the Treasury of the United States. The law requires that each container of Serum sold by licensed establishments shall bear upon the label, in addition to the name of the Serum, the name, address and license number of the manufacturer, and the date beyond which the contents cannot be expected to yield its specific results. The label should also contain the laboratory number of the Serum, the name and the percentage by volume of the antiseptic used (if such

be used) and the total number of antitoxic units claimed for the contents of the container.

Serum Antidiphthericum Purificatum.—A solution in physiological solution of sodium chloride of certain antitoxic proteins obtained from the blood serum or plasma of a horse, actively immunized against diphtheria toxin. After the serum or plasma from the immunized horse has been collected, the non-antitoxic proteins are removed by precipitation with ammonium sulphate and by dissolving the precipitate in saturated sodium chloride solution, the salts being then removed by dialysis. After dialysis is complete, sufficient sodium chloride is added to make an 0.8 percent. solution. Preserve in sealed glass containers in a dark place, at a temperature between 4.5° and 15° C. A transparent or slightly opalescent liquid, with sometimes a slight granular or ropy sediment, odorless, or having an odor due to the presence of the antiseptic used as a preservative. The liquid is sometimes more or less viscous. The serum must come from healthy animals; must be sterile; must be free from toxin or bacterial products and must not contain an excessive amount of preservative (0.5 percent. phenol or 0.4 percent. cresol, when such are used); and the total solids should not exceed 20 percent. Serum of a lower potency than 250 units per cubic centimeter is not to be sold. Other requirements as under Serum Antidiphthericum.

Serum Antidiphthericum Siccum.—Dried Diphtheria Antitoxin is obtained by the evaporation of either Antidiphtheric Serum or Purified Antidiphtheric Serum in a vacuum, over sulphuric acid, or by passing over it a current of warm air freed from bacteria. Preserve in amber-colored glass containers free from air in a dark place, at a temperature between 4.5° and 15° C. The Dried Serum occurs either in the form of orange or yellowish flakes or small lumps, or as a yellowish-white powder, without odor. The serum is readily soluble in nine parts of distilled water. The solution is opalescent and slightly viscous. For use the Serum should be dissolved under the most rigid asepsis, preferably in the original container. Dried Antidiphtheric Serum does not lose in potency, as does the liquid Serum. Other requirements as under Serum Antidiphthericum.

Serum Antitetanicum.—A fluid separated from the coagulated blood of a horse, *Equus Caballus Linne'*, highly actively immunized against tetanus toxin. Preserve in sealed glass containers in a dark place, at a temperature between 4.5° and 15° C. A yellowish or yellowish-brown transparent or slightly turbid liquid with sometimes a slight granular sediment, odorless, or having an odor due to the presence of the antiseptic used as a preservative. Antitetanic Serum gradually loses its potency, the loss being greater at higher than at lower temperatures. The Serum must come from healthy animals; must be sterile; must be free from toxin or bacterial products; and must not contain an excessive amount of preservative (0.5 percent. phenol, or 0.4 percent. cresol, when such are used); and the total solids should not exceed 20 percent. Only such Serums may be sold as have been prepared and propagated in establishments licensed by the Secretary of the Treasury of the United States. The law requires that each container of Serum sold by licensed establishments shall bear upon the label, in addition to the name of the Serum, the name, address, and license number of the manufacturer, and the date beyond which the contents cannot be expected to yield its

specific results. The label should also contain the laboratory number of the Serum, the name and the percentage by volume of the antiseptic used (if such be used) and the total number of antitoxic units claimed for the contents of the container. The standard of strength, expressed in units of antitoxic power, shall be that established by the United States Public Health and Marine Hospital Service.

Serum Antitetanicum Purificatum.—A solution in physiological solution of sodium chloride of certain antitoxic proteins obtained from the blood serum or plasma of a horse, *Equus Caballus* Linné, and actively immunized against tetanus toxin. After the Serum or plasma from the immunized horse has been collected, the non-antitoxic proteins are removed by precipitation with ammonium sulphate and dissolving the precipitate in saturated sodium chloride solution, the salts being then removed by dialysis. After dialysis is complete, sufficient sodium chloride is added to make an 0.8 percent. solution. It should be kept in sealed glass containers in a dark place, at a temperature between 4.5° and 15° C. A transparent or slightly opalescent liquid, with sometimes a slight granular or ropy sediment, odorless, or having an odor due to the presence of the antiseptic used as a preservative. The liquid is sometimes more or less viscous. The Serum must come from healthy animals; must be sterile; must be free from toxin or bacterial products; and must not contain an excessive amount of preservative (0.5 percent. phenol or 0.4 percent. cresol, when such are used), and the total solids should not exceed 20 percent. Other requirements as under Serum Antitetanicum.

Serum Antitetanicum Siccum.—Dried Tetanus Antitoxin is obtained by the evaporation of either Antitetanic Serum or Purified Antitetanic Serum in a vacuum, over sulphuric acid, or by passing over it a current of warm air freed from bacteria. It should be kept in amber-colored glass containers free from air in a dark place at a temperature between 4.5° and 15° C. The Dried Serum is either in the form of orange or yellowish flakes or small lumps, or a yellowish-white powder, without odor. The Serum is readily soluble in nine parts of distilled water. The solution is opalescent and slightly viscous. For use the Serum should be dissolved under the most rigid asepsis, preferably in the original container. Dried Antitetanic Serum does not lose in potency, as the liquid Serum does. It is sometimes used as a dusting powder or for local application to infected wounds. Other requirements as under Serum Antitetanicum.

Virus Vaccinicum.—The pustules of vaccinia or cowpox removed, under aseptic conditions, from vaccinated animals of the bovine species. It should be kept in a dark place, at a temperature between 4.5° and 15° C. The vaccine pulp should be thoroughly rubbed up in a mortar or passed through a special grinder, strained to remove coarse particles, and made into a smooth emulsion with a glycerin solution. Vaccine Virus gradually loses in potency, the loss being more rapid at high temperatures than at low temperatures. Only such Vaccine Virus may be sold as has been prepared in establishments licensed by the Secretary of the Treasury of the United States. It is required by the law and the regulations now in force that the following requirements be observed. No Vaccine shall be used from any animal having a communicable disease, or suspected of having a com-

municable disease, other than vaccinia; animals used for propagating Vaccine Virus must be under daily veterinary examination for a period of not less than seven days before vaccination, and as soon as the vaccine pulp is removed a necropsy shall be made on each animal and permanent records kept of the same. Each and every lot of Vaccine Virus shall be examined to determine its freedom from pathogenic micro-organisms and a special examination must be made of each lot to determine the absence of tetanus spores or toxin, and permanent records must be kept of these examinations. The Virus must be marketed in sterile containers that comply with the requirements of the law and the regulations established by the United States Government mentioned above. Each package of Vaccine Virus shall bear upon the label the name, address and license number of the manufacturer and the date beyond which the contents cannot be expected to yield their specific results. The label should also contain the laboratory number of the Virus.

VOLATILE OILS.

The following article replaces the U. S. P. VIII text for Oil of Sweet Birch, Oil of Gaultheria and Methyl Salicylate.

Methylis Salicylas.—A product yielding, when assayed by the process given below, not less than 98 percent. of methyl salicylate ($\text{CH}_3\text{C}_7\text{H}_5\text{O}_3=152.06$). It is produced synthetically or obtained by distillation from *Betula lenta* Linné (Fam. Betulaceæ) or from *Gaultheria procumbens* Linné (Fam. Ericaceæ) and the source from which it is derived in every case must be stated on the label. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light. It is a colorless, yellowish or reddish liquid, having the characteristic odor and taste of Gaultheria. Specific gravity at 25° C.: Synthetic 1.180 to 1.185; when from Sweet Birch or Gaultheria 1.172 to 1.180. Boiling Point: 218° to 221° C. Synthetic Methyl Salicylate, or that from Sweet Birch, is optically inactive; when obtained from Gaultheria, it is slightly laevogyrate, not exceeding -1.5° in a 100 mm. tube at 25° C. Sparingly soluble in water; soluble in all proportions in alcohol and glacial acetic acid. It is soluble in 6 volumes of 70 percent. alcohol at 25° C. with not more than a slight cloudiness. The alcoholic solution is neutral or slightly acid to moistened litmus paper. A deep violet color will be produced by shaking a drop of Methyl Salicylate with about 5 Cc. of distilled water and adding a drop of ferric chloride T. S. Add 10 Cc. of potassium hydroxide T. S. to 1 Cc. of Methyl Salicylate, contained in a capacious test-tube, and agitate the mixture. A clear, colorless or faintly yellowish solution results, without the separation of any oily drops either on the surface or at the bottom of the liquid (other volatile oils or petroleum). It does not respond to the Volatile Oil Heavy Metals Test. *Assay for Methyl Salicylate*: Introduce about 2 Cc. of Methyl Salicylate into a tared flask, note the exact weight, add 50 Cc. of half-normal alcoholic potassium hydroxide V. S., connect the flask with a reflux condenser and heat the mixture on a water-bath during two hours. Then add a few drops of phenolphthalein T. S. and titrate the excess of alkali with half-normal hydrochloric acid V. S., noting the amount required. This shows, when calculated from the weight of the sample originally taken, not less than 98 percent. of methyl salicylate.

Oleum Amygdalæ Amaræ.—A volatile oil obtained by maceration and distillation from the ripe kernel of *Prunus Amygdalus* Stokes var. *amara* DeCandolle (Fam. Rosacæ), and from other kernels containing amygdalin, the source from which it is derived in every case to be stated on the label; yielding not less than 85 percent. of benzaldehyde and not less than 2 percent. nor more than 4 percent. of hydrocyanic acid. This Oil is intended for medicinal use; it is not to be used for flavoring foods. Specific gravity changed from "1.045 to 1.060" to "from 1.038 to 1.060" at 25° C. Added requirement: Refractive index: 1.5428 to 1.5439 at 20° C. "Optically inactive" changed to "optically inactive or dextrogyrate, not exceeding +0° 10' in a 100 mm. tube at 25° C." Soluble in "equal volume of 70 percent. alcohol" changed to "dissolves, forming a clear solution, in 2 volumes of 70 percent. alcohol." The test for presence of hydrocyanic acid and the flame test for chlorinated products omitted. Added test: Add 10 drops of the Oil to a little alcohol, introduce a small amount of zinc dust and 2 Cc. of acetic acid and boil the mixture for a short time; no odor of phenyl isonitrile should develop after rendering it strongly alkaline with potassium hydroxide T. S., adding a drop of chloroform and heating (nitro-benzene). *Assay for Benzaldehyde*: Dissolve 3 Gm. of phenylhydrazine (not darker in color than pale yellow) in 50 Cc. of alcohol and titrate 25 Cc. of the solution with half-normal hydrochloric acid V. S., using methyl orange T. S. as indicator, to a distinct change in color. To about 1 Gm. of Oil of Bitter Almond, accurately weighed, add 25 Cc. of the phenylhydrazine solution just prepared and titrate the mixture after thirty minutes with half-normal hydrochloric acid V. S. as just described. The difference between the number of cubic centimeters of half-normal hydrochloric acid V. S. required in the two titrations, multiplied by 0.053 will show the weight of benzaldehyde present. Always freshly prepare the phenylhydrazine solution when required for the assay. *Assay for Hydrocyanic Acid*: Dissolve 15 Gm. of crystallized magnesium sulphate in enough distilled water to measure 100 Cc., add 5 Cc. of this solution to 40 Cc. of distilled water, 5 Cc. of half-normal sodium hydroxide V. S. and two drops of potassium chromate T. S. and titrate the solution with tenth-normal silver nitrate V. S., to the production of a permanent reddish tint. Pour this mixture into a 100 Cc. flask containing about 1 Gm. of Oil of Bitter Almond, accurately weighed, and titrate again with tenth-normal silver nitrate V. S. until a red tint, which does not disappear on shaking, is reproduced.

Oleum Anisi.—A volatile oil distilled from the ripe fruit of *Pimpinella Anisum* Linné (Fam. Umbelliferae), or from the ripe fruit of *Illicium anisatum* Linné (Fam. Magnoliaceæ), conforming in name to the plant from which it is derived. Specific gravity: Changed from "0.975 to 0.988" to "from 0.978 to 0.988 at 25° C." Added: Refractive index: 1.5440 to 1.5600 at 20° C. "Laevogyrate up to -2°" changed to "optical rotation varies from +1° to -2° in a 100 mm. tube at 25° C. (oil of fennel)." "Soluble in an equal volume of alcohol, forming a clear solution, also in 5 volumes of 90 percent. alcohol" changed to "soluble with not more than a slight cloudiness in 3 volumes of 90 percent. alcohol." Cool the oil in determining congealing point to 12° C. instead of 6° C. It does not respond to the Volatile Oil Heavy Metals Test as follows:

Volatile Oil Heavy Metals Test.—Shake 10 Cc. of the oil with an equal volume of distilled water and pass hydrogen sulphide through the mixture until it is saturated; no darkening in color will be produced in either the oil or the water (lead or copper).

Oleum Aurantii Corticis.—Obtained by expression from the fresh peel of *Citrus Aurantium sinensis* Gallezio (Fam. Rutaceæ) and its varieties. Added: Refractive index: 1.4723 to 1.4737 at 20° C. Dextrogyrate—"not less than 95°" changed to "not less than 94°." Added test: Introduce 50 Cc. of Oil of Orange Peel into a 200 Cc. three-bulb Ladenburg flask of approximately the following dimensions: The lower or main bulb 6 cm. in diameter with the smaller condensing bulbs 3.5 cm., 3.0 cm. and 2.5 cm. in diameter, respectively; with the distance from the bottom of the flask to the side arm 20 cm. Distil the Oil at the rate of one drop per second until 5 Cc. has been obtained. The angle of rotation of the first 10 percent. of the distillate thus obtained is equal to or slightly greater than that of the original sample. The refractive index of this first 10 percent. of distillate is not less than 0.0008, nor more than 0.0015 lower than that of the original sample at 20° C. Nitrosolimonene test for added Oil of Turpentine omitted.

Oleum Cadinum.—Added specific gravity: 0.980 to 1.055 at 25° C. "Completely soluble in ether" changed to "Completely soluble in 3 volumes of ether, amyl alcohol, chloroform, glacial acetic acid, or oil of turpentine, but only partly soluble in petroleum benzin." Added tests: One part of the Oil of Cade shaken with 20 parts of warmed distilled water and filtered, yields a filtrate which gives with a few drops of ferric chloride solution (1 in 1000) a red coloration. Portions of this aqueous filtrate reduce silver nitrate in the cold and Fehling's solution on heating. An aqueous filtrate from a mixture with Oil of Cade (1 in 20) produces no red coloration on the addition of a few drops of aniline (wood tar products); another portion of the aqueous filtrate is not colored by the addition of potassium chromate T. S. (coal tar products). Agitate 1 Cc. of Oil of Cade with 15 Cc. of purified petroleum benzin, filter the benzin solution, add an equal volume of copper acetate solution (1 in 20), shake the mixture and then allow it to separate. On adding an equal volume of ether to the separated benzin solution, it produces no intensely green coloration and does not become colored more than from a light yellow to brown (rosin and rosin oil).

Oleum Cajuputi.—Distilled from the fresh leaves and twigs of several varieties of *Melaleuca Leucadendron* Linné, especially the var. *Cajuputi* Roxburgh and the var. *minor* Smith (Fam. Murtaceæ). Rubric and assay for cineol content omitted. "Colorless or greenish liquid" changed to "colorless or yellowish liquid." Specific gravity changed from "0.915 to 0.925" to "from 0.912 to 0.925 at 25° C." Laevogyrate—"not exceeding —2°" changed to "not exceeding —4° in a 100 mm. tube at 25° C." Added test: It does not respond to the Volatile Oil Heavy Metals Test.

Oleum Cari.—Yielding not less than 50 percent., by volume, of carvone, "Soluble in an equal volume of alcohol, also in from 3 to 10 volumes of 80 percent. alcohol" changed to "soluble in 8 volumes of 80 percent. alcohol. Assay for Carvone: Introduce 10 Cc. of the Oil into a 200 Cc. flask, with a

long, graduated neck, by means of a graduated pipette, add 50 Cc. of a saturated solution of sodium sulphite, which has been carefully neutralized by means of acetic acid containing a few drops of phenolphthalein T. S., heat the mixture in a bath containing boiling water and shake the flask repeatedly, neutralizing the mixture from time to time by the addition of a few drops of diluted acetic acid. When no coloration appears, upon the addition of a few more drops of phenolphthalein T. S. and heating for fifteen minutes, bring the residual oil into the neck of the flask by the further addition of the sodium sulphite solution and ascertain its volume. The difference in volume between this residue and the volume of the original oil (10 Cc. multiplied by 10), is equivalent to the percentage by volume of the carvone present.

Oleum Caryophylli.—Distilled from the flower-buds of *Eugenia Aromatica* (Linné) O. Kuntze *Jambosa Caryophyllus* (Sprengel) Niedenzu (Fam. Myrtaceæ). Rubric changed from "80 percent." to "82 percent." of eugenol. Specific gravity: Changed from "1.040 to 1.060" to "from 1.038 to 1.060 at 25° C." Added test: Slightly laevogyrate, not exceeding $-1^{\circ} 10'$ in a 100 mm. tube at 25° C. Tests with potassium hydroxide solution or ammonia water and with ferric chloride T. S. omitted. In the assay the mixture of 50 Cc. of potassium hydroxide T. S. and 10 Cc. of oil, after shaking it for five minutes, is heated on a water-bath for ten minutes to complete the reaction.

Oleum Chenopodii.—Distilled from *Chenopodium ambrosioides anthelminticum* Linné (Fam. Chenopodiaceæ). Added tests: Specific gravity: 0.955 to 0.980 at 25° C. It is laevogyrate, varying between -4° and -10° in a 100 mm. tube at 25° C. It is soluble in 8 volumes of 70 percent. alcohol.

Oleum Cinnamomi.—Distilled from the young twigs of *Cinnamomum Cassia* (Nees) Blume (Fam. Lauraceæ), rectified by steam distillation. Rubric changed from "75 percent." to "80 percent." of cinnamic aldehyde. Specific gravity changed from "1.045 to 1.055" to "from 1.045 to 1.063 at 25° C." "Almost optically inactive" changed to "optical rotation varies from $+1^{\circ}$ to -1° in a 100 mm. tube at 25° C." Hydrogen sulphide test replaced by "It does not respond to the Volatile Oil Heavy Metals Test." Lead acetate test for rosin replaced by the following: Shake 2 Cc. of the Oil in a test-tube with from 5 to 10 Cc. of purified petroleum benzin and decant the latter. This liquid is colorless and does not give a green color upon shaking with an equal volume of copper acetate solution (1 in 1000) (rosin). *Assay for Cinnamic Aldehyde*: Assay as for carvone under *Oleum Cari*.

Oleum Coriandri.—Specific gravity: Changed from "0.863 to 0.878" to "from 0.863 to 0.875 at 25° C." Optical rotation changed from " $+7^{\circ}$ to $+14^{\circ}$ " to " $+8^{\circ}$ to $+13^{\circ}$ in a 100 mm. tube at 25° C." It is soluble in 3 volumes of 70 percent. alcohol. Solubility in 80 and 90 percent. alcohol omitted.

Oleum Cubebæ.—Optical rotation changed from " -25° to -40° " to "from -20° to -40° in a 100 mm. tube at 25° C."

Oleum Eucalypti.—Distilled from the fresh leaves of *Eucalyptus Globulus* Labillardière (Fam. Myrtaceæ) or from other species of *Eucalyptus*. Rubric changed from "50 percent." to "not less than 70 percent." of eucalyptol. "Soluble in all proportions in alcohol; also soluble in 3 volumes of 70 percent. alcohol"

changed to "soluble in 4 volumes of 70 percent. alcohol." Optical rotation omitted. *Assay for Eucalyptol* (replacing former assay): Introduce 10 Cc. of the Oil into a 100 Cc. flask with a long, graduated neck (cassia flask) by means of a graduated pipette, add enough of an aqueous solution of resorcinol (1 in 2) to fill the flask about four-fifths full. Shake the mixture thoroughly for five minutes and then bring the residual oil into the neck of the flask by the further addition of the same strength resorcinol solution, rotating or gently tapping the flask, if necessary, to cause the oil to rise to the surface. When the resorcinol solution has become clear (usually after standing for several hours) ascertain the volume of the residual oil. The difference in volume between this residue and the volume of the original Oil (10 Cc.) multiplied by 10, is equivalent to the percentage, by volume, of the eucalyptol present. When Oils are rich in eucalyptol, dilute the 10 Cc. taken for the assay with an equal volume of oil of turpentine, before applying the test, to avoid crystallization in the resorcinol solution.

Oleum Fœniculi.—Distilled from the ripe fruit collected from cultivated varieties of *Fœniculum vulgare* Miller (Fam. Umbelliferae). Added test: Optical rotation varies from $+12^{\circ}$ to $+24^{\circ}$ in a 100 mm. tube at 25° C. "Soluble in an equal volume of alcohol; also soluble in 10 volumes or less of 80 percent. alcohol" changed to "soluble in 8 volumes of 80 percent. alcohol and 1 volume of 90 percent. alcohol." Congealing point changed from "not below 5° C." to "not below 3° C." Proceed as directed under *Oleum Anisi*, cooling the Oil to 0° C.

Oleum Hedeomæ.—Distilled from the flowering plant of *Hedeoma pulegioides* (Linné) Persoon (Fam. Labiatae). Optical rotation changed from $+18^{\circ}$ to $+22^{\circ}$ to "from $+17^{\circ}$ to $+28^{\circ}$ in a 100 mm. tube at 25° C." Added to solubility requirement, "forming a solution showing not more than a slightly acid reaction with litmus."

Oleum Juniperi.—Distilled from the ripe fruit of *Juniperis communis* Linné (Fam. Pinaceae). Specific gravity changed from "0.860 to 0.880" to "from 0.854 to 0.879 at 25° C." Added tests: The optical rotation varies from 0° to -15° , in a 100 mm. tube at 25° C. It is soluble in 4 volumes of alcohol with not more than a slight cloudiness.

Oleum Lavandulae.—Distilled from the fresh flowering tops of *Lavandula vera* DeCandolle (*Lavandula officinalis* Chaix, *Lavandula spica* Linné) (Fam. Labiatae). Specific gravity changed from "0.875 to 0.910" to "from 0.875 to 0.888 at 25° C." Added tests: The optical rotation varies from -1° to -10° in a 100 mm. tube at 25° C. Shake 20 Cc. of the Oil with 40 Cc. of 5 percent. alcohol and when the mixture has cleared withdraw 30 Cc. of the alcoholic solution. Neutralize this with half-normal potassium hydroxide V. S., using phenolphthalein T. S. as indicator, then add 5 Cc. of half-normal potassium hydroxide V. S., and heat the mixture on a water-bath under a reflux condenser during one hour. Not less than 4.7 Cc. of half-normal hydrochloric acid V. S. is required for neutralization after saponification.

Oleum Limonis.—Obtained by expression from the fresh, ripe peel of *Citrus medica* Linné variety *Limonum* (Risso) Hooker filius (Fam. Rutaceae). Added test: Refractive index: 1.4744 to 1.4755 at 20° C. Optical rotation changed from "not less than $+58^{\circ}$ " to "from $+57^{\circ}$ to $+64^{\circ}$ in a 100 mm. tube at 25° C." Added test: The angle of rotation of the first 10 percent. of the Oil, obtained by

distillation, as described under *Oleum Aurantii Corticis*, is not more than 5° less than that of the original Oil. The refractive index of this first 10 percent. of distillate is not less than 0.0020 nor more than 0.0027 lower than that of the original oil at 20° C. *Assay for Citral*: (Replacing former assay.) Introduce about 15 Cc. of Oil of Lemon into a tared 300 Cc. flask, by means of a pipette, and note the exact weight; add 10 Cc. of a solution of phenylhydrazine (not darker in color than pale yellow) in alcohol (1 in 10), and allow it to stand for one-half hour at room temperature. Then add a few drops of methyl-orange T. S. and neutralize the liquid exactly by the cautious addition of half-normal hydrochloric acid V. S. If difficulty is experienced in detecting the end point of the reaction, carry the titration until the solution is distinctly acid, transfer it to a separatory funnel and draw off the alcoholic portion. Now wash the Oil with distilled water, adding the washings to the alcoholic solution, and titrate the latter with half-normal potassium hydroxide V. S. Carry out a blank test identical with the foregoing except that the Oil of Lemon is omitted, and note the amount of half-normal hydrochloric acid V. S. consumed. Subtract the number of cubic centimeters of half-normal potassium hydroxide V. S. from the number of cubic centimeters of half-normal hydrochloric acid V. S. used in the original test and this result from the corresponding number of cubic centimeters required in the blank test; each cubic centimeter of this difference corresponds to 0.076 Gm. of aldehydes, calculated as citral.

Oleum Menthae Piperita.—Distilled from the flowering plant of *Mentha piperita* Linné (Fam. Labiatae), rectified by steam distillation. Ester content in rubric changed from "6 percent." to "not less than 5 percent." Laevogyrate changed from " -20° to -33° " to "from -20° to -35° in a 100 mm. tube at 25° C." Solubility in alcohol and reaction to litmus omitted, and "no separation of oil globules" added to solubility in 70 percent. alcohol statement. Modified test: Distil about 1 Cc. from 25 Cc. of the Oil and pour the distillate on an aqueous solution of mercuric chloride (1 in 25); a white film does not form at the zone of contact within one minute (dimethyl sulphide—found in non-rectified oils). *Assay for Esters and Total Menthol*: Ten Cc. of the original oil is taken for the menthol assay instead of the washed residual oil from the menthyl acetate assay; otherwise the assay remains unchanged.

Oleum Menthae Viridis.—Distilled from the flowering plant of *Mentha spicata* Linné (*Mentha viridis* Linné) (Fam. Labiatae). Added rubric: Yielding not less than 40 percent., by volume, of carvone. Laevogyrate changed from " -35° to -48° " to "from -35° to -50° in a 100 mm. tube at 25° C." *Assay for Carvone*: Assay as directed for carvone under *Oleum Cari*.

Oleum Myristica.—Specific gravity changed from "0.884 to 0.924" to "from 0.859 to 0.924 at 25° C." Added test: Optical rotation varies from $+14^{\circ}$ to $+30^{\circ}$ in a 100 mm. tube at 25° C. Modified test: Evaporate 3 Gm. of the Oil on a water-bath; not more than 0.06 Gm. of residue should remain.

Oleum Picis Liquidæ.—Specific gravity changed from "about 0.892" to "from 1.012 to 1.065 at 25° C." It is soluble in alcohol, the solution showing an acid reaction with litmus.

Oleum Pimentæ.—Specific gravity changed from "1.028 to 1.048" to "from

1.018 to 1.048 at 25° C." Added test: Its optical rotation varies from 0° to —4° in a 100 mm. tube at 25° C. "Miscible in all proportions in 90 percent. alcohol" changed to "soluble in an equal volume of 90 percent. alcohol." *Assay for Eugenol*: Assay as directed under *Oleum Caryophylli*.

Oleum Pini Pumilionis.—A volatile oil distilled with steam from the fresh leaves of *Pinus montana* Miller (*Pinus Pumilio* Haenke) (Fam. Pinaceæ). It is a colorless or faintly yellowish colored oil having a pleasant, aromatic odor, and a bitter and pungent taste. Specific gravity: 0.853 to 0.869 at 25° C. No portion of the Oil distils below 170° C.

Oleum Rosmarini.—Solubility in 90 percent. alcohol omitted. *Assay for Ester and Total Borneol*: Assay as directed under *Oleum Menthæ Piperitæ*, the Oil of Rosemary factors remaining unchanged.

Oleum Santali.—Optical rotation changed from "—16° to —20°" to "from —15° to —20° in a 100 mm. tube at 25° C." Soluble in 5 volumes of 70 percent. alcohol, forming a solution having a slightly acid reaction with litmus. Solubility in alcohol omitted. *Assay for Santalol*: Assay as directed under *Oleum Menthæ Piperitæ*, using the factors under Oil of Santal, but changing "11.026" to "10.926."

Oleum Sassafras.—Distilled from the root of *Sassafras variifolium* (Salisbury) O. Kuntze (Fam. Lauraceæ). Specific gravity changed from "1.065 to 1.075" to "from 1.065 to 1.077 at 25° C." Optical rotation changed from "not more than +4°" to "from +3° to +4° in a 100 mm. tube at 25° C." Added test: Soluble in 2 volumes of 90 percent. alcohol, forming a solution neutral to litmus.

Oleum Sinapis Volatile.—A product yielding, when assayed by the process given below, not less than 92 percent. of allyl iso-thiocyanate ($\text{CSNC}_3\text{H}_5 = 99.12$). It is produced synthetically or obtained from the seed of *Brassica nigra* (Linné) Koch (Fam. Cruciferae) (freed from fatty oil) by maceration with water and subsequent distillation, and must conform in name to the source from which it is derived. Added test: Optically inactive. Modified tests: The Oil completely distils between 148° and 154° C., and both the first and last portions have nearly the same specific gravity as the original Oil (alcohol, chloroform, petroleum, and fatty oils). The addition of a drop of ferric chloride T. S. to the Oil, diluted with several volumes of alcohol, does not produce a blue coloration (phenols). *Assay for Allyl Iso-thiocyanate*: Connect the flask with a reflux condenser when heating the mixture as directed in the assay for one hour—otherwise the process remains unchanged.

Oleum Terebinthinæ Rectificatum.—The freshly distilled Oil is to be dried by shaking it with anhydrous calcium chloride, and filtering. Specific gravity changed from "0.860 to 0.865" to "from 0.856 to 0.865 at 25° C." "No weighable residue on evaporation of 10 Cc." changed to "not more than 0.010 Gm. of residue."

Oleum Thymi.—Distilled from the flowering plant of *Thymus vulgaris* Linné (Fam. Labiatae). Specific gravity changed from "0.900 to 0.930" to "from 0.894 to 0.929 at 25° C." Optical rotation—"not more than —3°" omitted. "Soluble in half its volume of alcohol and in 1 volume of 80 percent. alcohol" omitted; "soluble in 2 volumes of 80 percent. alcohol" retained. The test with ferric chloride to show a greenish-brown color omitted. *Assay for Phenols*: The assay is to be conducted in a flask with a long, graduated neck instead of in a burette.

BICHLORIDE OF MERCURY TABLETS AND BICHLORIDE TABLET LEGISLATION.*

GEORGE M. BERINGER, PH. M.

In presenting a paper on such a hackneyed subject as Bichloride of Mercury Tablets and Bichloride Tablet Legislation, I am well aware that I may be trying your patience on a subject that you may perhaps consider as threadbare. My association with and study of this subject, however, convinces me that this is not a dead subject, but that it contains several problems directly associated with the duties of the druggist and which pharmacists themselves, in a very large measure, must decide.

The extensive use of corrosive sublimate in this form has justified the decision of the Committee of Revision of the U. S. P. to introduce an official formula, and by this means to endeavor to provide additional safeguards to life in their use. The articles that have appeared in the medical, pharmaceutical and lay press, as well as the discussion in the committee, demonstrate that this is a live subject and associated with it are several questions still to be settled.

In the official recognition of the tablet of mercuric chloride, the U. S. P. is only following the example of most of the pharmacopœias that have been revised in recent years. A study of the foreign formulas and a comparison of these, and likewise of the commonly used American formulas, is interesting.

In American practice, either Wilson's formula, containing a mixture of mercuric chloride and ammonium chloride, or Bernay's formula, containing mercuric chloride and citric acid, have been almost exclusively used. In Europe the formula proposed by Angerer, for *Pastilla Hydrargyri Bichlorati*, has been the type followed. His formula is the following:

PASTILLI HYDRARGYRI BICHLORATI.

Mercury bichloride.

Sodium chloride.....aa 0.5 Kg.

Eosin 1.0 Gm.

Mix the salts and color the mixture with the eosin dissolved in water. Allow the mixture to dry in the air and compress into portions, weighing one or two grammes each.

The German Pharmacopœia IV (1900), and, again in the fifth edition (1910), adopts the title "*Pastilli Hydrargyri Bichlorati*" and directs that, from a mixture of equal parts of mercuric chloride and sodium chloride colored with a red coal tar dye, are to be made cylinders twice as long as thick and weighing 1 or 2 gm. each. Sublimate pastilles must be dispensed in sealed bottles labelled "Poison," and each pastille must be wrapped in black paper on which is printed, in white, the word "Poison" and the content of mercuric chloride stated in grammes.

The Swedish Pharmacopœia (1901) under the title of "*Pastilli Chloreti Hydrargyrici*" directed that "Sublimate pastilles" should be hard cylinders or prisms, weighing either 1 or 2 gm. each, and composed of equal parts of mercuric

*Read before the New Jersey Pharmaceutical Association, Lake Hopatcong, N. J., June 17, 1914.

chloride and sodium chloride and colored red by an aniline dye. It, likewise, introduced the requirement, that each tablet must be wrapped in black paper, on which was printed in white the word "Poison."

The Austrian Pharmacopœia (1906), under the title "Pastilli Hydrargyri Bichlorati Corrosivi," directed that equal parts of mercuric chloride and sodium chloride should be triturated to a thorough mixture and colored with a solution of eosin and compressed in pastilles weighing 1 gm. to 2 gm. The pastilles are directed to be dispensed in glass bottles, under a poison-label, and the pastilles are to be singly wrapped in black paper with the word "Poison" imprinted in white.

The Swiss Pharmacopœia, (1907), adopted as a title "Hydrargyrum Bichloratum Compressum," and, as a synonym, "Pastilli Sublimati." The formula is mercuric chloride 666 gm., sodium chloride 333 gm., eriocyanin, A, 1 gm., mixed and compressed into tablets weighing 37.5 cg., 75 cg. and 1.5 gm., and containing, respectively each 25 cg., 50 cg. and 1 gm. of corrosive sublimate. It directs that each tablet must be wrapped in black paper on which is printed, in white, the weight of the sublimate contained, the word "Poison" and a death's-head design.

The British Pharmaceutical Codex, in the first edition of 1907, and likewise in the 1911 edition, gave formulas for a series of these tablets. Under the name of "Solvellæ Hydrargyri Perchloridi,—Soluble Mercuric Chloride Tablets," and, as synonymous, "Antiseptic Perchloride, or Corrosive Sublimate Tablets,"—it directed a mixture of equal parts of mercuric chloride and sodium chloride colored with methyl violet, to be compressed into tablets containing 8.75 grains of the mercuric chloride, so that one dissolved in the imperial pint (20 fl. oz.) of water, will make a one-tenth percent (1 in 1000) solution of mercuric chloride. Under the title "Solvellæ Hydrargyri Perchloridi Fortes," or "Strong Soluble Mercuric Chloride Tablets," a tablet of the same percentage of essential ingredients, but double the weight, was directed, so that one tablet dissolved in twenty fluid ounces of water makes one-fifth percent (1 in 500) of mercuric chloride. Other formulas are given for a "mild" and for a "small" soluble mercuric chloride tablets, yielding, when dissolved as directed, solutions containing 1 in 4000 and 1 in 4500, the latter being especially recommended as suitable for ophthalmic purposes.

The French Pharmacopœia (1908), presented a new style of formula for use of mercuric chloride in antiseptic solution. Its formula for "*Papier au Chlorure Mercurique*" or "*Charta hydrargyri bichlorati*" directs that 5 gm. each of mercuric chloride and sodium chloride be dissolved in a sufficient quantity of distilled water to obtain a volume of 20 cc. Filter paper, purified by treating with water containing one part of hydrochloric acid to the thousand, washing with pure water and drying, is then saturated with the mercuric chloride solution, so that each rectangular surface, 5 cm. by 10 cm., shall imbibe 1 cc. of the solution and represent 25 cg. of mercuric chloride. The superscription "Corrosive Sublimate, twenty-five centigrammes," is directed to be printed with indigo-carmin, thus producing, when immersed in the proper volume of water, a blue solution. The paper is to be protected from light and moisture, and the container is to be labeled in indelible red letters "Poison."

These specifications of the *Pharmacopée Française*, official in that country since July 17, 1908, yields a product essentially the same as the corrosive sublimate leaflets now being made by an American manufacturer, who claims originality and the right to a patent thereon as a new and novel invention.

The Italian Pharmacopœia (1909), gives the title "*Pastiglie di Cloruro Mercurico*," with the Latin synonym, "*Pastilli Bichlorureti Hydrargyri*." The formula is mercuric chloride and sodium chloride equal parts, colored with an aqueous solution of eosin, and compressed into circular pastilles of 1 or 2 gm. in weight.

It is to be noted that most of the foreign pharmacopœias, have, simply, followed in their titles the nomenclature proposed by Angerer, and designate these tablets as "*Pastilles*." In the same pharmacopœias, the title "*pastilli*" is frequently applied to mild remedial agents dispensed in the form of confections or lozenges. It is certainly an unfortunate designation and a dangerous classification that would include such a toxic form along with worm-lozenges, cough-troches, peppermint-drops, etc. It is still more to be regretted that it has been proposed to adopt this same title in the U. S. P. IX. The use of the word "*pastille*" in this connection is not in accordance with the English usage of this word. As defined in the dictionaries, the word "*pastille*" refers to several forms of substances of an entirely different character and dissimilar use.

The Century Dictionary defines "*pastille*" or "*pastil*"—

"1—a small roll of aromatic paste, composed of gum benzoin, sandal wood, spices, charcoal powder, etc., designed to be burned as a fumigator.

"2—a kind a sugared confection, usually of a strong flavor, of a round flat shape, like peppermint drops.

"3—in art: (a) a thin round cake of watercolor; (b) the method of painting with watercolors prepared as pastils or a drawing produced by them.

"4—In pyrotechny: a paper case filled with a burning composition intended to cause rotation of a wheel."

Neither of these definitions would comprise a mercuric chloride tablet of the shape described, or its intended use. In medicine and pharmacy, this title had already been pre-empted and used to a considerable extent for medicated confections, and its adoption, for such a toxic official preparation, is an exceedingly dangerous experiment. It was probably for this reason that the Pharmacopœia Helvetica adopted as its title, "*Hydrargyrum Bichloratum Compressum*," and the British Pharmaceutical Codex, "*Solvellæ*." The "*Solvellæ*" of the Codex, are compressed tablets or discs intended to be dissolved in water for external or local use. The attempt at classification here made, is a step in the right direction. The title coined, however, does not include the toxic character of the product, and, moreover, is subject to the criticism that it has the appearance of an attempt to imitate the trade-marked name of a certain brand of tablets extensively used in England.

The necessity is for a distinct title that will clearly differentiate between the medicinal tablets used so extensively for internal administration, and poisonous tablets intended for external use. The safeguarding of life is the first and principal consideration, and this warrants the coining of a new title, that shall distinguish the latter as a separate and distinct class. For this purpose, I propose *Toxibellæ* as a distinctive class title, and as the official title for these

tablets, *Toxitabellæ Hydrargyri Chloridi Corrosivi*, and as the English, *Poison Tablets of Corrosive Mercuric Chloride*.

The foreign formulas follow the formula of Angerer, in directing equal parts of mercuric chloride and sodium chloride. The American manufacturers generally claim on their labels to adhere to the Wilson formula. Tablets containing the proportion of ammonium chloride directed in this latter formula, are prone to change on keeping. They deliquesce in humid atmospheres and the solubility also lessens with age. For these reasons, some of the manufacturers have already substituted sodium chloride for part of the ammonium chloride. One manufacturer advises that he has found preferable a mixture of corrosive sublimate 7.3 parts, ammonium chloride 2.7 parts, sodium chloride 5 parts. The entire replacement of the ammonium chloride by sodium chloride will doubtless yield a more stable and soluble tablet, and this change should be adopted in the pharmacopœial formula.

The coloring of bichloride of mercury antiseptic tablets, was originally proposed, not only to make them distinct in color from other tablets of the same shape and size, but the primal idea was to obtain a solution that would have a distinct color and not be mistaken and administered for harmless medications or for water. Such accidents had occurred and to prevent their recurrence, Angerer proposed, as an additional safeguard, that solutions of corrosive sublimate should be colored. It has been difficult to select a red dye that would possess sufficient tinctorial-strength, so that only a minute quantity of the coloring agent would be required, and at the same time would be permanent and not altered by the action of the chemicals nor fade on keeping. This problem has confronted the manufacturers and has been the subject of considerable experimentation on the part of the writer.

Eosin, in the quantity proposed, yields a tablet that is distinctly pink, but when in solution (1 in 1000) it does not show a distinct color. This practical difficulty with the red dyes, their variable shades, and, moreover, the fact that confections are frequently of this color and liquid medicines are likewise, commonly, some shade of red, has led to the use of other colors. The British Pharmaceutical Codex directs methyl violet, which, in this combination, gives a blue-purple solution. The Swiss Pharmacopœia orders eriocyanin A, the sodium salt of a suphlonated dye of the triphenyl-methane-carbinol type, that colors silk and wool a bright blue, and is only slightly affected by 10 percent. hydrochloric acid. The French Codex directs Indigo-Carmine for this purpose.

A number of the manufacturers are already giving preference to the blue tablets. One of these manufacturers writes: "Green and red-colored tablets are not at all satisfactory. I believe that you will agree with me that a somber blue would prove the most desirable. Confections are made in red, green, yellow, white and every conceivable color, but the blue is not attractive and, therefore, would in all probability prove the safest."

On the question of coloring for mercuric chloride, Dr. A. G. Rosengarten, whose firm prepares large quantities of mixed salts, already colored for the manufacturers, writes me:

"The only satisfactory color that we have found is blue dye, called indigo-

carmine. We have not yet found a satisfactory red or green dye, but I can highly recommend indigo carmine for consistent results, and a definite weight of that dye added to a definite weight of corrosive sublimate mixture, will produce definite results. I cannot say the same about the other dyes, and I think it will be most desirable to confine the dyes for corrosive sublimate mixture to the one color, blue, and the one dye, indigo-carmine."

My own experiments confirm these statements as to the availability of indigo-carmine for this purpose. 2.5 mg. per tablet is sufficient to color 500 Cc. of water a distinct blue. If a more intense color be desired, this can be increased up to 5 mg. and the quantity to be specified in the formula for 100 tablets should not exceed .5 gm. In my experiments with red dyes, iod-eosin and alizarin carmine (sodium alizarin sulphonate) appear to have given the best results, with the Wilson type, but the color of the solutions is not as bright a red as might be desired. With the Bernay formula, containing citric acid, methylorange has shown the best results.

The official tablet should be adjusted to the basis of one tablet to 500 Cc. of water, yielding a 1 in 1000 solution, instead of one tablet to the pint, as has been the custom. This will necessitate only a slight increase in the weight.

The shape to be adopted for the official "Bichloride Tablets" is one of the questions that is being considered. When these tablets were introduced, the manufacturers, quite naturally, used the moulds already in use, and so the unfortunate mistake was made of manufacturing these poisonous tablets of the round or disc shape; the same shape and size as were used for innocuous medicinal tablets and confections. Fatal accidents, attributable in part to the shape, have demonstrated that it is imperative that this dangerous practice should be discontinued. Toxic tablets of the bichloride of mercury antiseptic type, should be made in a unique shape, one that has not been used for any other purpose, and the use of such a shape or form should be restricted, by legal enactments, to toxic tablets intended for external use.

In recent years, the ingenuity of the American manufacturer has been exercised to obtain a distinctive shape that should characterize and distinguish his brand of "antiseptic tablets." As a result, we now have such shapes as the triangle, diamond, square, cube, keystone, and clover leaf, exploited as proprietary forms of antiseptic tablets. Every one of these shapes has been commonly used in confections and their official recognition and continuance for bichloride antiseptic medication would be a repetition of the original fatal error as to the shape of such tablets. The manufacturers of these shapes are each clamoring for the recognition of his particular shape.

The influence of these commercial interests has been exerted to prevent legislative action that would designate an appropriate shape, or judicial consideration that would permit judgment to crystallize in favor of an official shape, that would insure the greatest amount of protection to life. After all, the question of "safety first" is the paramount question.

Of all the proposals for a shape for bichloride of mercury tablets, the coffin shape suggested by Mr. F. M. Apple in his paper before the Pennsylvania Pharmaceutical Association seems to be best. This has already been adopted by at least four manufacturers, and its general adoption has only been prevented by

the commercial interests back of other designs. Commercial instincts and financial advantage, and not the broad humanitarian principle of what is best to protect life, have been the causes actuating the opposition to legislation and to the official recognition of the best suggestion yet offered.

The German Pharmacopœia has been quoted, as an authority to be followed in fixing the U. S. P. standard. I believe that we should appropriate from the foreign pharmacopœias all that our experience and judgment prove to be correct and in accordance with American practice. In this instance, I cannot approve of following the *dictum* of the German Pharmacopœia. I have a sample of the official German Corrosive Sublimate tablets that have been in my possession since last March. These are not uniform in color and fading has commenced to take place. The shape is in conformity with that of the Ph. Gr., twice as long as broad, and the manufacturer to show this, and possibly to permit of economy, in using only half a tablet at a time, has made them with a ridge across the centre. This makes them resemble forms of the pink, linked phenolphthalein, and other proprietary, laxative wafers, that are so extensively used in this country. It would be difficult to conceive of a more dangerous experiment, than to officially recognize such a shape for bichloride tablets. It would be on a par with the adoption of the Italian Pharmacopœial standard of the round tablet, which we are now ready to condemn. There is no uniformity in the European pharmacopœias regarding these tablets, and so the argument, for the adoption of an international standard, falls flat. The solution of these tablets, when made of a strength of 1 to 1000, as commonly used, is of so delicate a pink tint as to be barely perceptible.

So far as I know, no American manufacturer has yet placed on the market, a bichloride of mercury tablet copied after that of the German Pharmacopœia. As this formula has been published for more than fourteen years, this is noteworthy, and may be construed as an evidence of the good judgment of our manufacturers. To now insist, that the U. S. Pharmacopœia should adopt and make legal, a shape that has not met favor in American practice, is a unique proposition that lacks the popular approval that is essential to its effectiveness.

The importance of throwing every safeguard possible around the sale and handling of such poisonous substances, is now thoroughly recognized. The newspapers have given wide publicity to the deaths, either suicidal or accidental, occurring from bichloride tablets. The evils resulting from the overzealous newspaper, which gives its readers all the details of the method by which some poor unfortunate has gone on the long voyage, have been discussed and decried, yet nevertheless it continues its course with little or no abatement.

A number of State legislatures, in session during the past year, have had under consideration, laws that would restrict the handling of such poison tablets, and which would define their shape, color and label, and further prohibit the use of the prescribed shape for any other purpose. There are, at least, three bills, on the same subject, now pending in Congress. It is certain that we may expect legislation before long on this entire matter, and it is eminently proper that the drug trade should take an active interest in solving a question of public safety that is so closely associated with our business. Unfortunately, the atti-

tude assumed by some of the druggists is that of thoughtless indifference. The argument advanced by others is that such legislation is only a passing sentimental fad and that it can have no influence on the protection of life. This is so fallacious, that it can not long continue to prevent legislation.

It was never expected that any legislation would prevent a person of morbid mind from committing suicide. This is not the purpose of the proposed legislative enactments, but it is contended that, in prescribing a distinctive shape for these poison tablets, they could under no circumstances be mistaken, either in the day or night, for harmless medications. If a distinctive shape had been supplied the Macon, Ga., banker and the Brooklyn business-man, whose deaths, beyond question, were accidental poisonings, at least these lives could have been spared. The necessity for a distinctive shape for Bichloride of Mercury Tablets is well shown by the compilation appearing in Public Health Report No. 46, by Martin I. Wilbert of the United States Public Health Service. In this compilation, Mr. Wilbert shows that, at that time, in the current price-lists of five leading pharmaceutical manufacturers, there were sixteen different formulas and varying sizes of poison bichloride tablets, five different shapes, five different colors, and only three, out of the sixteen, were then made of any other shape than the ordinary round tablet used for internal medication, such as headache and cold tablets. Could any stronger evidence of the necessity for restrictive legislation and a distinctive shape for these poison tablets, be presented, than this compilation in a government bulletin, which shows the present dangerous and unsatisfactory method of marketing these tablets?

The influence of certain manufacturers on proposed legislation, is shown in the act passed by the last session of the Maryland Legislature. Instead of specifying in the act a distinctive shape or color, the value of the legislation enacted is largely nullified by the amended form in which the bill was passed. This law provides that "tablets containing more than 1/10 grain of Mercury Bichloride, must be of either triangular, diamond, square, oblong or other irregular shape, and their color must be either blue, purple, or green, with the word "Poison" imprinted or embossed on each tablet." Further, these tablets can only be sold, dispensed or given away, in bottles, upon one side of which the word "Poison" has been blown, and with a label with the word "Poison" placed on the face of the bottle.

The restrictions regarding the package and labeling, are such as are commonly employed by all of the manufacturers, but the very needed protection *to the consumer*, has been lost sight of, by the overpowering commercial-spirit that prevented the selection of a distinctive shape for the tablets. Any one of a number of shapes, is equivalent to no shape, and the very indefiniteness of the act as passed destroys its value as a measure for the safety of the public.

MAGNESIA MAGMA—MILK OF MAGNESIA, N. F.

SAMUEL T. HENSEL, PH. G.

While the formula for Magnesia Magma (Milk of Magnesia, N. F.) is calculated upon the basis of chemical equivalence, that is to say, the magnesium sulphate and sodium hydroxide are in molecular proportion; yet owing to the method of procedure given in the National Formulary, the resulting precipitate forms a semi-translucent, viscous mass, difficult to pour from a bottle, and far from being the snow-white cream which it is intended to obtain.

President George M. Beringer, published an article, about a year and a half ago, in the *Journal of the A. Ph. A.*, in which he laid down the fundamental principles necessary for success in the manipulation of this process and I am indebted to his article, for the success I have had in the manufacture of this preparation.

The principal features of Mr. Beringer's process are as follows:

First—That the solutions of magnesia sulphate and sodium hydroxide must be brought to the boiling point before mixing.

Second—That the solutions should be mixed in reverse order to that given in the National Formulary; the magnesium sulphate solution being slowly added in a fine stream, with continued stirring, to the solution of sodium hydroxide.

Third—That the sodium hydroxide must be in excess to the extent of 10%.

Fourth—Distilled water is directed.

My experience in the manufacture of this preparation has led me to make two changes in the process, first, with respect to the percentage of sodium hydroxide used, and second, as to the nature of the water employed for the purpose of washing the precipitate.

In the course of my experience, I first observed that the amount of the precipitate obtained, was not constant. The cause of this I traced to a variation in the strength of the sodium hydroxide that I was using, this being the product of three different manufacturers.

I then found that in order to wash the precipitate with distilled water until the supernatant liquid should no longer become cloudy upon the addition of a drop of T. S. Barium Chloride, would increase the cost of production to such a point as to make its use prohibitive.

I, therefore, increased the amount of sodium hydroxide to 12%, and on some occasions to 15%, and also adopted the use of water supplied by our artesian well, which is of exceptional excellence, and which furnishes one of the best potable waters to be found anywhere.

The foregoing reasons have therefore prompted me to make the following modifications.

First—Owing to the variations in yield of precipitate obtained by the use of different samples of sodium hydroxide, I have increased the amount indicated by the theoretical molecular formula, from 12 to 15%. This ensures that when

the residual product is reduced to a volume of 1000 Cc., as directed by the National Formulary, each fluid ounce will contain 24 grs. of magnesium hydroxide $\text{Mg}(\text{OH})_2$.

Second—Artesian water is used for washing the precipitate to the amount that each gallon of magma is washed with about twenty-eight gallons of water.

In preparing the solutions necessary for one gallon of magma the magnesium sulphate is first dissolved in one gallon of water, the solution filtered and then boiled. The sodium hydroxide is dissolved in 6 pints of water, and this solution filtered and boiled. The solution of magnesium sulphate is then poured, in a thin stream, and with constant stirring, into the solution of sodium hydroxide, and the resulting mixture boiled vigorously for 15 minutes or more. There is no danger of over-heating the mixture, for the reason that the magnesium element can be exposed to a far greater degree of heat than can be imparted by boiling, without injury.

After the mass has been thoroughly boiled, the mixture of the solutions is diluted with water to 5 gallons, and allowed to stand for twenty-four hours, or until subsidence has taken place to about the one gallon level, which should be previously marked on the container. The exact level is unimportant, however, as my experience demonstrates that the quantity indicated above, will reach its maximum level in twenty-four hours. The supernatant liquid is then carefully drawn off by means of a rubber tube syphon; fresh water is added, and the washing continued in this manner for the requisite time.

The reaction which takes place in this process is represented by the following equation:

The following equation indicates that the molecular quantities of the N. F. are theoretically correct, but the peculiarities of mass-action were evidently not considered; these however, are governed by concentration, temperature and various other influences, which can only be overcome by experience in operative work.

	Grams	Combined Mol. Wt.	Water
$\text{Mg SO}_4 + 7\text{H}_2\text{O}$	250	244.69	+ 3 H_2O
	—	=	—
2NaOH	81	79.52	

A striking illustration of chemical action bearing upon this subject is revealed during the preparation of zinc iodide ZnI_2 . If we take the atomic weight of metallic zinc 64.9, and mix it with the combining atomic weight of iodine 125.9×2 , introducing these two substances into a flask together with a half fluid ounce of distilled water, there will be an immediate re-action, shown by the color which will deepen and become more and more intense as the re-action proceed; followed in a few minutes by an appreciable increase in temperature, up to a certain point, when the heat of the re-action is suddenly enormously increased, and a portion of the iodine is volatilized, as is indicated by the violet-colored vapor which is evolved; the whole mixture in the meantime, becoming involved in violent ebullition. The temperature then gradually subsides, the mass be-

comes cold, chemical action ceases, and no amount of subsequent agitation will discharge the color of the iodine, although it is still in the presence of uncombined metallic zinc.

The cause of the suspension of chemical reaction in the above mixture is due to three conditions, namely, concentration of the solution, diminution of the area of the surface of the metallic zinc, and absence of heat.

If, on the other hand, we employ a considerable excess of metallic zinc, using the atomic weight of iodine as before, the very largely increased area of zinc-surface exposed to the action of the iodine, enables combination to proceed regardless of concentration, up to the point of the complete discharge of the iodine color, thus indicating complete chemical union of the two elements.

In the case of Magnesia Magma, for the same reason, chemical equivalents should not be used; but we must have an excess of sodium hydroxide, in order that the magnesium sulphate may be completely decomposed. This is evident from the amount of that salt found in the supernatant liquid when less than an excess of sodium hydroxide is employed.

URINE ANALYSIS; QUANTITATIVE ESTIMATION OF GLUCOSE.

JOSEPH L. MAYER.

Any one who has occasion to make many quantitative determinations of sugar in urine, is aware of the necessity of having a rapid, accurate and easily applied method of analysis.

Shortly after the publication of Benedict's paper, "The Detection and Estimation of Glucose in Urine" I began experimenting with the object of ascertaining the accuracy of the method.

The sugar in a sample of urine was determined volumetrically by employing the following modification of Benedict's method, which I suggested in a paper read at the last annual meeting of the American Pharmaceutical Association (Journal A. Ph. A., May, 1914, page 687).

Into a 100 cc. Erlenmeyer flask, with cord wrapped around the neck to prevent burning the fingers, pour 25 cc. of accurately measured Benedict's Quantitative Solution, add a few grammes of crystallized sodium carbonate and place on the hot plate. When the solution is boiling, gradually add the sugar solution from a burette, with sufficient slowness to allow the reaction to proceed, putting the flask back on the hot plate until disappearance of color.

The sugar in this same sample, was then determined gravimetrically, by the following method of Defren-O'Sullivan (Leach, Food Inspection and Analysis, 2nd edition, page 564):

Mix 15 cc. of Fehling's Copper Solution with 15 cc. of the Tartrate Solution in a quarter liter Erlenmeyer flask and add 50 cc. distilled water, place the flask and its contents in a boiling water bath and allow them to remain five minutes, then run rapidly from a burette into the hot liquor in the flask, 25 cc. of the sugar solution to be tested (which should contain not more than one-half percent

*Read before the New York State Pharmaceutical Association, June 23, 1914.

of reducing sugar). Allow the flask to remain in the boiling water-bath, just fifteen minutes after the addition of the sugar solution, remove, and with the aid of a vacuum, filter the contents rapidly into a platinum or porcelain Gooch Crucible containing a layer of prepared asbestos-fiber about 1 gm. thick, the Gooch, with the asbestos, having been previously ignited, cooled, and weighed. The cuprous oxide precipitate, is thoroughly washed with boiling distilled water until the water ceases to be alkaline.

(The asbestos should be of the long-fibered variety and should be especially prepared as follows: Boil first with nitric acid (sp. gr. 1.05 to 1.75) washing out the acid with hot water, then boil with a 25 percent solution of sodium hydroxide, and finally wash out the alkali with hot water. Keep asbestos in a wide-mouthed flask or bottle, and transfer it to the Gooch, by shaking it up in the water and pouring it quickly into the crucible while under suction.)

Dry the Gooch with its contents, in the oven, and finally heat to dull redness for fifteen minutes, during which the red cuprous-oxide is converted into the black cupric-oxide. After oxidation as above, the crucible is transferred to desiccator, cooled, and quickly weighed. From the milligrams of cupric oxide, calculate the milligrams of dextrose from table accompanying the method.

The results by both methods were as follows:

Gravimetric	2.806% sugar
Volumetric	2.777% sugar
<hr/>	
	.029% difference

Another sample of urine tested by the same methods contained, by the

Gravimetric method....	6.34 % sugar
Volumetric method.....	6.29 % sugar
<hr/>	
	.05 % difference

These results clearly indicate that the volumetric method of Benedict modified as above, while rapid and easily applied, is capable of yielding just as accurate results as the longer gravimetric method.

I am now conducting a series of experiments, to determine the relative accuracy of all the methods commonly used to quantitatively determine glucose in urine, and hope in the near future to publish the results of same.

THE SIXTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION.

M. I. WILBERT, PH. M., WASHINGTON, D. C.

The 1914 meeting of the American Medical Association was held in Atlantic City June 22-26 and 3,958 members registered as present at the convention. This registration is reported to have been considerably larger than that of any of the previous sessions of the Association in Atlantic City. The work of the House of Delegates and its committees, and the proceedings of the several Sections of the Association are reported at length in the Journal of the American Medical Association for July 4, 1914, v. 63, p. 73-130. The scientific papers, because of the restrictions imposed by the House of Delegates at the Minneapolis meeting, were fewer in number than in former years but the subject matter dis-

cussed was correspondingly good, the programs for the several Sections being generally well carried out.

The Section on Pharmacology and Therapeutics had as usual a program containing many papers of pharmaceutical interest. Delegates from the American Pharmaceutical Association were recognized and Prof. Joseph P. Remington, the Chairman of this Delegation, in extending the felicitations of the organization he represented, said:

"The American Pharmaceutical Association brings greetings to the American Medical Association. It is meet and proper that two National bodies should exchange greetings for however they may differ in function and scope, they are united in principle in the one great object of promoting the health of the Nation in combating disease.

"It is gratifying to know that the Pharmacopœia is practically completed so far as the bulk of the work is concerned. The printing of the Appendix with the Tables, Reagents and Volumetric Solutions will be sent to the printer this week, for this part of the book must be printed first, in order that members may have it for reference in checking up the text of the book.

"During the past year a number of older remedies have been deleted and new remedies admitted. The Committee on Scope, which reports upon proposed admissions and deletions, have finished their work but there are still a few questions which can be settled after the printing is started. One of these questions is the form of so-called Bichloride Tablets. As is well known, the enormous use of these Tablets is a menace to the future growth and prosperity of the Nation. The Pharmacopœia cannot check the use of these Tablets, but it can at least direct the form for their use which will tend to prevent accidental administration.

"The American Pharmaceutical Association during the past year has used its influence in every possible way to control and limit the use of habit-forming drugs.

"The body which I have the honor to represent, asks the assistance of your body to aid in framing wise laws which will make it difficult for 'dopesters' to continue their habits, and to limit the use of these drugs to the legitimate use of properly educated physicians.

"In educational matters Pharmacy has progressed by raising the standard of education of those entering Pharmacy, and enlarging the curricula of the colleges. May we not hope that Medicine and Pharmacy will be more closely linked in the future, and that crimination and recrimination will cease, or take the form of constructive criticism, with the intention of remedying the evils and correcting abuses, and inculcating harmony between the two professions."

Referring more particularly to the probable scope of the U. S. P. IX, the following table represents its status at the present time:

Number of articles in text of U. S. P. VIII.....	958
U. S. P. VIII articles deleted in Revision	237
U. S. P. articles retained in Revision.....	721
Number of new articles admitted to U. S. P. IX.....	67
Total number of articles in tentative list of U. S. P. IX.....	788

On motion of Dr. Murray Galt Motter, of Washington, D. C., the Section on Pharmacology and Therapeutics of the American Medical Association, adopted the following resolution which was referred to the House of Delegates, and endorsed by that body, thus becoming officially recognized as the opinion of the American Medical Association:

"WHEREAS, The Pharmacopœia of the United States of America should be, above all, a book designed to protect the public health and prevent the exploitation of the sick and afflicted for profit; now, therefore be it

"*Resolved*, That the members of the Section on Pharmacology and Therapeutics of the American Medical Association, request the House of Delegates to urge upon the Revision Committee, to make official in the Pharmacopœia of the United States 'corrosive mercuric chloride pastilles' so that physicians may not be compelled to prescribe this remedy under a proprietary name; be it further

"*Resolved*, That this Section endorses the form and description of corrosive mercuric chloride pastilles, as described in the German Pharmacopœia, namely, of cylindrical shape, twice as long as thick, wrapped individually in paper bearing the name of the medicament 'corrosive mercuric chloride pastilles' and the word 'poison' in suitable and striking letters; be it further

"*Resolved*, That a copy of this resolution be forwarded by the Secretary of the American Medical Association to the President and to each of the officers of the United States Pharmacopœial Convention and also to the Chairman and to each member of the Committee of Revision of the Pharmacopœia of the United States."

Of the many papers presented in the Section on Pharmacology and Therapeutics the following contributions were of more immediate interest to pharmacy:

Dr. John F. Anderson, the Chairman of the Section on Pharmacology and Therapeutics, in his address, discussed some unhealthy tendencies in therapeutics and referred more particularly to the ill-advised use of certain biologic products such as the Friedman vaccine for tuberculosis, and crotalin in the treatment of epilepsy. In summing up this paper, he suggested that, while advances in therapeutics are necessary and clinical trials must be made, these trials should be with adequate controls of otherwise treated cases, and under circumstances in which every stage can be watched and the various clinical and laboratory observations be made a matter of unbiased record and the best interests of the patients thus safeguarded. It is difficult to secure these conditions outside of a well-equipped hospital. Until a new method of treatment has received abundant confirmation of this sort it is unjust—to use no stronger word—to apply it promiscuously to patients who are not under constant observation and are not amenable to instant emergency relief.

In a paper on "The Medical Treatment of Chronic Intestinal Stasis," W. A. Bastedo, of New York, discussed the uses and limitations of many of the aperients and cathartics. In commenting on the now widely-used paraffine oil, he called attention to a series of ten samples, not one of which complied strictly with the requirements of the Pharmacopœia, and also stated that, in writing prescriptions for paraffin oil or liquid petrolatum, it is unfortunately true that it is practically necessary to specify some established brand, as the material supplied in retail drug-stores very seldom, if ever, complies with the requirements of the Pharmacopœia.

In a paper on Active Immunization in Diphtheria by toxin-antitoxin mixtures, William H. Park, of New York, reported on recent progress in the prophylaxis of diphtheria, and reviewed the present-day knowledge regarding immunization, and the possible recognition of immunization by skin reaction.

In a paper on the use of diphtheria antitoxin in the treatment of diphtheria, Samuel S. Woody, of Philadelphia, recommended the administration of much larger doses than are used at present, and stated that the number of antitoxin units to be administered, should be in keeping with the stage of the disease. He said that, as a prophylactic diphtheria antitoxin was uncertain, and in a great measure unsatisfactory in its results, and that to be efficacious in the treatment of diphtheria, antitoxin must be given at the earliest possible moment and in large doses.

In addition to the resolution endorsing the inclusion of pastilles of corrosive mercuric chloride in the Pharmacopœia of the United States, the House of Delegates also adopted the following recommendation of pharmaceutical interest, suggested by the Council on Medical Education and endorsed by the reference committee:

"Your committee also recommends that the Council be instructed to urge all medical colleges to adopt the nomenclature of the Pharmacopœia of 1910 and to use the metric system in their teaching."

The scientific exhibit was of unusual interest and the work displayed was not alone excellent, but much of it was of immediate practical value to the profession. The commercial exhibit attracted considerable attention, and was unusually free from objectionable features in the way of proprietary and semi-proprietary preparations not recognized by the Council on Pharmacy and Chemistry.

The officials for the Section on Pharmacology and Therapeutics for the coming year, are: Chairman, R. H. Hatcher; Vice-Chairman, J. Ray Arneil; Secretary, M. I. Wilbert; Delegate, John F. Anderson, and Alternate, Ray E. Wilbur.

At the opening meeting of the Association on Tuesday morning, Dr. Victor C. Vaughan, of Ann Arbor, Michigan, was installed as President, and at the concluding session of the House of Delegates, on Thursday afternoon, Dr. Wm. L. Rodman, of Philadelphia, was selected as the president-elect and San Francisco chosen as the place of meeting for 1915.

BEEF IN 1740.

A writer in the Yale Review who notes that in 1740 beef could be bought in Boston at twelve cents a pound seems to imply that that price was all it was worth. "Invariably a steak for dinner was heralded by the vigorous pounding with the potato masher wielded by the stalwart arm of the cook." The meat, in fact, often came, he tells us, from the carcass of "a cow that no longer gave milk or a bull that had lost its bloom." Still there were many Englishmen in Boston in the eighteenth century, and they must have been able to obtain somewhere roast beef that was worthy of their exacting palates.

ADDRESS TO THE GRADUATING CLASSES OF THE COLLEGE OF
PHYSICIANS AND SURGEONS, SAN FRANCISCO, JUNE 4, 1914.*

R. CADWALLADER, A. M., M. D., PROFESSOR OF OBSTETRICS AND ASSOCIATE PROFESSOR
OF ABDOMINAL SURGERY, COLLEGE OF PHYSICIANS AND SURGEONS OF
SAN FRANCISCO.

It has been twenty-one years since I took my degree in medicine and twenty-five since I first began its study. During this time more radical changes have taken place than in any equal period of recorded history. I began my work in a rural community, in competition with men far older than I, who were typical old-school practitioners. Bridging then, as I do the past, pre-aseptic days with the present aseptic school, it seems natural for me on such an occasion as this to grow reminiscent. Allow me therefore to picture to you the physician of the past, then point out a few of the peculiarities of the present and, with the aid of both the past and the present, forecast the type of man who will be successful in the future.

The doctor of the old school is almost an extinct species. A few yet remain on the outskirts of civilization. They have been shot at so often that they have become very retiring and shy. Like the buffalo and the grizzly bear, the encroachments of modern life have pushed them to the background where a few forgotten specimens eke out a precarious existence, although their race is run.

He was as a rule an ambitious farmer boy with a mastery of Ray's Fourth Part Arithmetic, McGuffey's Sixth Reader and Webster's blue-backed speller. He entered into an understanding with the nearest doctor and became his friend, pupil, attendant, hostler, and general factotum for a term of apprenticeship. He boiled down the home-made drafts, mixed the salves, assisted at bone-settings, read the four volume library consisting of Gray's *Anatomy*, Megg's *Obstetrics*, Flint's *Practice*, Gross's *Surgery*, and possibly Dalton's *Physiology*, and had his powers of observation stimulated and quickened under the tuition of his chief. After a few years he went to the nearest city for two winter-courses of six months' each, in some medical college, where he saw operations, did some dissecting and followed the bed-side teaching of a few prominent men. This was in those days thought to be a very thorough course. He then returned home, by agreement took over a lot of the practice of his preceptor, often married the latter's daughter, and the two men remained in close intimacy for years.

His practice was rural and scattered over many miles of country. Calls were made by horse and cart, or on horseback, according as the state of the roads permitted and all his drugs were carried in saddle-bags. Few, very few, ever remained in the cities or wished to do so. The growth of urban population is recent in our history. In my boyhood I saw the trains of prairie schooners that settled Kansas and from my father's place the unconfined range stretched westward to the Rocky Mountains.

*From the Pacific Medical Journal.

For at least twenty miles in all directions, often for a hundred, he alone was the dependence of the community in accident and sickness. He had to be familiar with every road, by-path, gate and ford in all that region, not only by day but in the darkest night, in rain, sleet, hail, snow, slush and mud. Swollen streams had to be forded, avoided, or swam. He had to know the possibilities of getting through and take the shortest practicable route to and from the home of sickness. No white-handed, soft-nurtured man could endure these hardships. His clothing was not of broadcloth and he never owned a silk hat or became addicted to cigarettes. He dressed in rough clothing and wore boots.

As he sprang from the people, so he went back to the people—to his own family, friends and neighbors and he had their welfare close to heart. His was a genuine love for them as well as for his life-work. The community instinctively recognized this and turned to him naturally for sympathy and help in sickness and distress, nor turned in vain. It was some such man, known and appreciated, that gave McLaren his inspiration for the character of William McClure.

Entering therefore into the closest relationships of life with his families, the physician of the past could, and usually did, wield a tremendous influence for weal or woe. The preacher, the doctor and the schoolmaster were the educated men of the hamlet. Magazines were nearly unknown and always very expensive, the literature obtainable was mainly limited to the omnipresent *Bible* and *Pilgrim's Progress*. This was not perhaps a loss, when we consider the mass of worse than trash now flooding the country. Newspapers were not in general circulation. Politics was taught from the stump, and by debates; seldom if ever were speeches deliberately read.

The doctor then was a power. His name was used to frighten bad children by threats of his mammoth doses of nauseous drugs, and his example was held up to all as a model of grace to emulate.

Such an education and life led to an exceptional cultivation of the observant faculties. His hospital-training was nothing to speak of and he had for years to keep learning until the early habit thus formed became a rule of his life. Right here is the secret of true progress—constant application and addition to the sum of knowledge by observation.

For nursing the sick he had to depend upon the neighbors when the family became tired out. It was thought to be a duty to sit up with the sick. I have known men and women to work hard all day and stay up all night with a neighbor, neglecting their own work and families, even when the afflicted was an enemy. They would have been much surprised had such acts been favorably commented upon. They did it—nay, thank God, they do it still—in numberless places. I have seen a life-long enemy who had quarreled and lawed many years, lay all this aside when his opponent's crushed body had to be taken over country-roads to the railroad, and beyond, for more skilful treatment. I have seen him stop his pressing work, go with all his hired men to shovel dirt over the jutting rocks and smooth the wheel tracks for the passage of a man to whom he would not have spoken a week before. Beneath the petty jealousies of life, beneath the anger and misunderstandings there are depths of feeling in our people that link them to the angels.

What these volunteer nurses lacked in training they made up in willingness, in cheerful service of any kind, in a life-long knowledge of the patient's whims and fancies. Often the women would slip over at such times and do all the housework for a day, get out a washing or do the ironing, send in the cooked food for weeks—all that the mother might have the time to hang over the bedside of a dying child. The beauty of this is that it is not uncommon or any credit taken for it—it was done regularly, quietly and for the transient stranger in his canvas-covered wagon as well.

The therapeutic agents used by the old doctor were never compounded with much regard to taste. There was a popular idea that to be effective the medication must be black and bitter. I have had to add a little quinine to many a prescription before the patient felt that he was getting what his illness needed. No small dose was ever thought to be as powerful as a draught. Tincture *Asafoetida* in teacupful doses was what was expected in hysteria and is not bad treatment to-day if coupled with a casual remark that the dose will be repeated in ten minutes if the patient does not feel better. One favorite in the spring was something like this: ten cents worth each of orris, powdered rhubarb, and dandelion roots, quinine, senna leaves, the bile from a fresh ox-gall in a quart of the very best whiskey—to be well shaken each time and the dose a wineglassful before meals. In most cases it worked beautifully, by lessening the appetite considerably.

A mild laxative which the children were expected to take was a tablespoonful of sorghum molasses stirred stiff with sulphur. To thin their blood in the spring, considered very indispensable, a teaspoonful of cream tartar was given. Sassafras tea was used exclusively for about forty penitential days every spring, and goose-grease, skunk-oil and turpentine held honored places in every cupboard. Straight galenicals alone were used and given absolutely empirically in the cases that experience had taught that they produced results.

The doctor was also the dentist. He never wasted valuable time in filling teeth but pulled every one that ached. Nor did he have an elaborate array of universal forceps. The old men had a hook and tackle that went over a tooth and flipped it out when operated by a ratchet. The men just preceding my time, had one or two pair of forceps and a shoemaker's awl for stumps, and generally got it out. Even bullet-moulds or pliers were impressed at times.

This old-school physician was not a specialist, far from it. Nor do I know exactly what a specialist is myself. Sometimes it seems as if he were a man who, while not knowing any more than any one else of some subject, knows nothing of any other. They were familiar with, and treated everything from abscess to zoster—they certainly had a broad vision. Statistics are not available, but I doubt whether the death-rate was very much higher then than now. The better treatment of to-day is offset by the poorer food, more unhygienic surroundings and the greater stress of life.

The principal evil he had to combat was the utter ignorance of the people on all sanitary and health measures. Superstition still lingers in many forms, but is not comparable with what was acted upon in those days. Potatoes had to be planted and butcherings done, by the moon, veterinary-surgery by the sign, and every

house had one or more almanacs behind the kitchen stove, each with its St. Sebastian-like figure on the front page.

Medicines were thought to be antidotal. The right dose "knocked out" the disease which was an entity. Cancer, for example, was a foreign body with long decapodia-like tentacles that dug into the victim and sapped his vitality. Patent medicines and Thompsonian remedies were implicitly believed in and taken by everybody in dozen-bottle lots. There was always a mad-stone, just in the next county, that sucked the poison from the mad dog's bite. When it had got it all, it would then drop off, and could be purified and made ready for the next case by boiling it in fresh milk; the milk turning green and often reported as killing a hog which carelessly had drank it up. Boils were thought to be good for a man, as removing bad humors from the blood. These were the days of blisters, bleeding, cupping and purging.

The doctor gathered many of his own medicines and boiled them down, on his office-stove, into drafts or poultices. He prepared his own surgical-dressings and held the sutures *in his mouth* until ready to put them in.

When I began my practice it was alongside of just such men as I have described. One of these used to wear home-made clothes of jeans, and his wife put in a row of four or five watch pockets, in which he carried calomel, gamboge, jalap and leptandrin. No matter what the complaint, the first demand was to see the tongue. Then he would take a pinch from each pocket, place in the palm of the left hand, and, with the aid of saliva, roll up a pill to be taken at once. I know the trials, the joys and the exposure of a country practitioner. That experience I would not exchange for any equal years since, so valuable were the lessons it taught me. It was hard to endure them, but now I know the meaning of that couplet, "*Forsan et haec olim meminise juvabit.*" (Perchance even these things it will be delightful to remember.) But for you, Oh! past generation, with all your faults, I have nothing but profound respect. Those men, certainly, had the golden triad of self-reliance, observation and sympathy for the suffering all around them.

The physician of to-day is a far better educated man. As a rule, he has one or more years of college-training added to a four years' course in a high-school and then four annual courses of professional training of nine months each. Often to this is added a year of internship or study abroad. Nor is he any too well *crammed* then, when he gets out. Instead of four years of medical study on a broad basis, we teachers waste at least one year in scientific studies that must be known, but which could better be taught before the real study of medicine is begun. By the time the young man is through with our modern six or seven years' work he is heartily sick of it all. Nor is the student crowded from the start as he should be. Any teacher knows that the whole four years could well be done in three, if continual and industrious study were enforced from the beginning. This long course means a decision too early in life, by a boy, immature, and unable accurately to decide what his bent really is. Too often the determination is made by parents, and results in another physician the more, who is temperamentally and mentally in friction with his calling.

The old-school doctor started his study because of a genuine love for the work

and at a mature age. He therefore learned faster, applied himself better, and his two short years were no doubt the equal of any two of to-day. Could I have the determining voice I would require better preparation, not longer in years of study, but in the subjects taken. Physics, chemistry, biology, etc., should all be mastered before the real work begins. It matters not where these are gained whether in a high school or a full college course, although a full college course is to be desired. He ought to be able to read one foreign language certainly. The trouble with our preliminary work is the inherited mediæval, scholastic ideal that sees no value in anything useful. Were the proper arrangement made the boy could get all this in a high-school. The requirement for entering a medical-school ought to be based on the subjects not on an arbitrary number of hours spent in what is often worthless as a preparation. I would not have him go directly to the medical college, but engage for a year or two in some employment, until his real desire to devote himself to medicine became a result of deliberate choice. We teachers can tell, every time when we get a student who has buffeted the world for a few years before starting medicine. He knows what he is there for, he is there to fit himself for a real life of which he knows something, and he is wasting no time in getting it. He is the man who keeps steadily at work, to whom graduation is not some far off point, with an unknown vista beyond. To such a man three years of medical study is sufficient, if to it a required year of internship is superimposed. If such a man begins his work at twenty-six or twenty-seven, it is soon enough, for medicine requires a maturity of mind seldom acquired earlier.

Our present schools are tending to paid instructors. Now a paid instructor never will or can be an enthusiast in any but one narrow field. He cannot know the medical requirements if he excels and limits himself to one line. He must spend his time in the repeated and wearying grind of hammering in basic principles, or else he must devote himself exclusively, as the majority do, in so-called research-work after the plan of our German *confreres* to the glory of his college but of little help to the students in it. In either event he is a failure. Such a man generally overshoots his audience or trains them into emulating him and his methods, until the student graduates a fine laboratory-man, but unfitted to do the world's work or see anything beyond the patient's excreta. The student in laboratory-work is constantly stimulating his dexterity, and exalting routine above mentality. Too much of it is narcotic in action. The right dose should be a stimulant to observation and thought. Just now it seems as if the pendulum had swung ridiculously far to the laboratory. Just now, also, there is a spasm of reform in medical teaching because of a growing feeling that we are not turning out men able to cope with the fads of half educated ignorance, the faith-curists, the unchristian and unscientific heresies so popular. If we fail in contact with these, the solution does not lie in increasing our already too great tendency to the recluse, or monastic type of education but in broadening out and getting into closer contact with the world and its needs, its heart-throbs, its sins, its joys and its alleviable misery.

This old world is a queer mixture of good and bad,—in body, mind and spirit,—throbbing for surcease. Only those in sympathy with it can treat it rightly,

"only those who sail the sea understand its mystery," and yet it is a good world, full of kindness, love and heavenly gleams of charity and it is constantly growing better—not worse.

The modern physician is an urban dweller. Few graduates plan to go back and live in a small community all their lives. The least they will do is to locate in a county seat. City life and larger population have lead to specialization. This is good, when it comes to a man of mature years, after considerable practice, naturally, and because of peculiar fitness for the work. But to see a callow youth, just out of school, drop from sight for a few months, return and at once announce himself as a surgeon or other specialist, is a sight for tears and pity. It is deplorable because it brings the genuine specialist, nay all medicine, into disrepute and belittles our high calling. Operate on me if you must, pass speculi and probangs, snare, cauterize or cut, but let it at least be done by a man who is able, by years of experience, to take in the whole situation at once and not one who can see nothing but some single orifice, and when he is done passes me on, for further examination.

There is a fault resulting from hospital work, that we see the disease and not the patient. Dealing with strangers all the time, creates a lessening sympathy with the individual. He becomes but another "case," valued only, and in proportion to, the rarity of his ailment and then treated in a routine and entirely impersonal manner. The public knows this instinctively. The many faddist schools of medicine, the foolish negation of any and all treatment, the hostility to physicians, the contemptuous criticism of them by the press, the jokes, sneers and the unwillingness to listen to or heed their efforts to help humanity, springs, I think, from a resentment of this impersonal attitude on our part. It is not formulated, but is none the less present. The modern physician has lost his love for his people and they cannot be expected to retain their love and respect for him.

With this lost respect, has departed the doctor's influence in the community. True, he is no longer one of the two or three educated men in the locality, and it is well that this is so. Still the varying schools of medicine, the changing treatment, the rapid advances and the public and free discussion of these, in the popular periodicals, leads to two results. Either seeing the differences among physicians, and having the audacity of ignorance that thinks itself wise, the laity doubt there being any permanent basis for the healing art and show a disposition to weigh for themselves every statement made to them by their doctor, or else they actually come to the conclusion that they are as well able to understand and prescribe as the man who has undergone years of special training for the business. These smattering journal-articles are a positive danger, while their number but emphasizes the public interest in the subject and the wide-spread need and dependence of the world upon the profession. They admit the need of physicians, but are unwilling to trust any one. As a result of this they wander from one to another aimlessly, swayed by every wind of doctrine, loudly condemning the men they left too soon for results to show, and at last, if kindly Nature, unassisted, works a cure, may later be loudly proclaiming in some experience-meeting how they were given up by all doctors as incurable and were cured by prayer, or some exorcizing formula beginning "God is good; good is God," Good God, etc.

Very remarkable has been the growth of the hospital idea in this country. Equally significant is the growing class distinction of them. Here in San Francisco the average hospital is beyond the income of the average man. If he strains a point and avails himself of it there is nothing left with which to pay his doctor. More and more are the poorer classes falling back on the City and County Hospital, thereby becoming stamped as indigents. There is a crying need for a hospital so managed in this city as to furnish decent attention at about half the present scale of prices. It would have the patronage of ninety percent of the population.

Again, no longer can the physician succeed who continuously gives large and bitter doses. The public palate has become very æsthetic and hence has sprung the great growth of pharmacy as a profession. This is natural and right; but let the physician limit himself to prescribing and the pharmacist confine himself to their proper preparation. There should be a most cordial relationship between the two. To the disgrace of both there are cases of rebating all the time. The sad feature of this is that it is not limited to the outcast physician but has in the ranks of these two-bit thieves many men who are members of the county medical society and who make themselves constantly conspicuous by howling for purer ethics and higher standards.

It is a hard life that you young men are entering upon. You will get precious little help from the older practitioners, some will even be actively hostile. The world at large thinks it knows a great deal and will be slow to receive you. A wave of disbelief is characteristic of the times. There is unrest and dissatisfaction politically, socially, religiously and medically. Few persons are uninfluenced by this and it shades from interference to hostility. New parties are formed, new religions started all as a protest against the old. At present the fad numerically largest are the followers of a neurotic old lady of more than doubtful moral character and reputation. Now anything that attracts so many, at least, semi-intelligent people, must have, in some form somewhere, a modicum of truth. It little behooves us to entirely condemn it until we have analyzed it. I believe it contains a world-old truth in a new form. It is religiously disguised because the churches have not taught the peace of mind that comes from a trust in God's providence as of old and many of these backsliders never were the "children of light." It is scientifically disguised as a reaction and rebuke to us, for our sins of omission. The world has asked us for bread and been given a stone. They came to us for comfort and advice, mental as well as physical, and we treated them as "cases" only, forgetting the mental suffering and the natural craving for personal sympathy. We have become materialists whereas we should be spiritists.

Years are bringing to me the belief that the unseen, the immaterial, the spiritual, if you will, the things that cannot be subjected to the proof of the senses are after all the only realities and the only things eternal. Treasure in heaven only is safe. Remember this fact, you who have listened so attentively to me these pleasant years. Be true to your higher duty and spare not yourself to help the world to better living and better ideals. Then you will at least be trusted and your councils followed.

A reliance on others, is another failure of the modern man. I welcome every

advance of knowledge but when a diagnostic method is discovered that requires special and expensive machinery, or is beyond the skill of the average man, it never appeals to me. One little hint, that we can all use, in backwoods' cabins and in the world's by-paths, is worth more than the surest test that depends upon the laboratory. Remember this, you who advocate the ultra-scientific school of medicine, that the time of your experts would be better spent in simplifying, making practicable and popularizing much of what we already know. Medicine cannot be advanced by a few brilliant minds, but by the surge forward of the profession as a whole. The history of medicine is full of revolutionizing discoveries, of brilliant generalizations published too soon and then forgotten for a generation or two, because the rank and file were not equal to their appreciation. Be not dependent upon the laboratory. We do not need any more or better-equipped school of original research work, two or three would supply the whole United States, but we do need schools that will train men for a life time of good work. We must not lose sight of the fact that the ninety-nine percent who graduate, must go into the small places and will not even remain in the cities, and it is our business to fit such men for their life work, not to train them for original work.

And so in contrast with the past it seems to me that the modern physician is characterized by a loss of self-dependence and resourcefulness, by a dependence upon the findings of others to line him in aright, by diagnostic methods too complicated for him to do, even had he the skill to read them, and more seriously by a lack of sympathy for, and understanding of anything, but the actual derangement that he diagnoses. I say this with modesty for I may be wrong; I am not so sure of many things as I was twenty years ago.

And lastly, what is to be the physician of the future, and what do I hope to see you become.

I would like to see the young man started under the supervision of a physician, and, because of his fitness for the life, and remain under the advice of the preceptor for years. His pre-medical course should be ample in sciences and such as to cultivate his powers of observation, whether it embrace a college course or high-school-fitness in subjects only being considered. In all spare time let him be with the older man. Let him take three strenuous years in a medical college whose teachers are men actually engaged in practice and finish with a year of internship, not merely as a superior head nurse, but with actual responsibilities. Then let the young man return to his own home and, if possible, close association with the preceptor, learning from his experience and imparting in turn the newer methods he has learned, and thus will both be improved.

Let the young man begin amid his own boyhood associates and in the country, where only he can get the broadest vision of his profession. He will start with the good will and love of many. We Americans move about too much. We miss the start and weight that comes from being a member of a family in good repute for generations. We need also to scatter out our bright young men, not to teach them to starve in a city, there to lose their enthusiasm and degenerate into shady practices because of the need of bread and butter, which is the lot of the majority who crowd the cities. To struggle into practice in San Francisco is a sordid lot. When I hear of some gifted young man ruined, because he

listened to temptation and is arrested for criminal practices, I remember my early struggles and the times when a dollar meant so much, as I worked away, without books, equipment, or even without knowing where the next suit of clothes or month's rent was to come from, and I have a sense of personal grief and pity for I know what he went through before his better nature yielded.

Enter into the vital life of your home. Be a *friend* and *neighbor* to your people and plan to live contentedly and die there. Gain the personal touch, and you will have the influence, and let this influence be always for the best.

The true physician must be a gentleman, to which are added all the Christian graces and the poise of culture. Only by real manhood and merit can you take your proper place in the world. Believe in the ultimate triumph of truth and in the coming of that time when the "righteousness of God shall cover the earth as the waters cover the sea." The world needs men of such ideals and will always reward them.

The teaching of our schools must become more personal and clinical. The patient behind the disease, must be pointed out by the instructor. Would that we teachers could have, just once, a student so well posted that we could ignore the symptoms and go deeper into the man behind.

Small, well-equipped and cheap hospitals should be available everywhere. From the richest to the poorest, the comfort should be the same. This may be done perhaps by combining the charitable and the paid institutions. Therapy will be a logical and definite aim. The details will be left more and more to the trained pharmacist and we will mutually help each other.

Specialists in the future will be men who have had a general practice but who, because of peculiar fitness are finding special work drifting to them and who have added to this, courses of special study for—not months—but years. For such men some competent source should give a special degree. The right to handle any case should always remain in the state license, but the public will appreciate an added degree, if honestly given.

Ignorance, poverty and crime will always exist, yet the future will bring a better appreciation of us as medical men but only when, and exactly to the extent, that we are true to our ideals. Let us waste no time in fighting false beliefs but in self-improvement. The clamor against lodge practice is a good deal of a joke and an evil only because men can be had who will take a whole family at a dollar a month. Often the very men who are crying most lustily for reform and who are "thanking God" like the Pharisee that "they are not like other men," are surgeons for some railroad or large corporation or hospital association—only larger lodges under other names. If one of these prominent men is going to do this work for one-tenth of what he would ordinarily collect, let him not blame a recent graduate if he takes a lodge for a mere pittance. If it be true as the author of David Harum makes that character say "a certain number of fleas is good for a dog because it keeps him from worrying because he is a dog"—then it will at least keep the young man from worrying because he has nothing to do. He will be busy scratching most of the time.

No other calling gives away so much or so cheerfully. No other calling by its effort is destroying its own source of livelihood. God grant that it may always

be so. If ever we put the love of the dollar above the call of distress let us cry with the daughter of Eli, "Ichabod, our glory is departed." Beyond its business side medicine has something immensurably greater.

Some day the world will wake up and, with the extra bounty born of regret at the delay, shower appreciation upon the martyrs we have ever been able to furnish in the hours of need. Men who allow themselves to be inoculated with deadly germs, who died to prove or disprove a theory whereby other lives by thousands can be saved to usefulness and happiness, deserve memorials of stone even more than the heroic souls who flushed with excitement and by the inspiration of numbers gave up their lives on fields like Gettysburg. I am proud of my profession. When fire and earthquake destroyed this city the State Medical Society was in session. Did those men go home to allay the natural fears of their families—mind you no word could be sent out and the apprehension was exaggerated. Not a man of them but stayed. They manned our hospitals, assisted our local surgeons, did yeoman work for days on our distributing bureaus, and visited the homeless in our parks until they saw we were able to handle affairs alone.

We have our faults, but the spirit of the profession needs but some emergency to see its members rise grandly to the occasion. More than any other profession or class they had the ability to handle that emergency. Trained to coolness in danger, calm of judgment amid excitement, familiar with distress, to discerning of motives, and knowing human nature, in no other walk of life could their equals be found and while others were criticized for poor judgment and extravagance, even speculation, tell me if you can a physician of repute who obtained a tainted dollar or did not give better than the average service. We were represented on every board and every committee and did a disproportional part of all the work.

The physician of the future will know that he knows. He will be self-reliant because he will be properly trained. He will be competent to diagnose with the best, he will do his own laboratory work and know how to read its findings aright in the light of the clinical picture.

Lastly, he will be a man of sympathy and appreciation of others. To each he will give his very best. Behind the symptoms he will see the terror-stricken soul. By council and example he will put him in a mental state for the healing forces of Nature to work unhindered. He will be a trusted friend in whose fidelity the sick one can with the utmost confidence rely. And when he cannot hold out the hope of cure he can relieve the pain, impart a confidence in the providence of God and a philosophy of life that will teach the dying man "to wrap the drapery of his couch about him and lie down to pleasant dreams."

And now, my new brethren in this profession, let me congratulate you on having reached so noble a position. This is, however, but the beginning of the real study of medicine. We have only taught you to a point where we feel that you can pursue your journey alone.

It is a life of hardship and poorly paid service. It has many inevitable disappointments but it also has many precious rewards. The love and affection of the family, the confidence in you that will lead the wife to confide to you secrets hidden from her husband, the faces of the sick brightening at your call—all this

you will know and in this you will find your chiefest reward. Like the great Physician you will be a man of sorrow and acquainted with grief. The depressing sights and sounds of suffering are not to be met by a case-hardening, but by a philosophy of life that is supreme optimism and which sees the beauty and the good in unexpected places. I would have you confident, self-reliant, and above all, sympathetic. With Polonius I say to you, "This above all—to thine ownself be true; and it must follow, as the night the day, thou can'st not then be false to any man." Much is expected of you—meet it, by being it, in reality.

Material wealth can hardly be expected to come to any of you, but riches of character will, if you have followed what I have ever taught. You may none of you reach fame or distinction, that is oftener a matter of chance than of forethought, it will make you no happier and may lessen your usefulness. Cultivate character, give freely, hold fast to your ideals, extend your help to the poor and after many years may you hear the words "well done, thou good and faithful servant."

These have been pleasant years that we have spent together. It is a rare and sacred privilege to mould the thoughts of any one. All my teaching has been done under the sense of this responsibility. Some day I shall pass on before you, for I am older than you. Then when you occasionally meet together speak kindly of me, and give others in turn a chance to do the same of you and so let a widening stream of kindnesses go down the years until we meet in that city of God whose strongest appeal to me is that "there shall be no death, neither sorrow nor crying, neither shall there be any more pain, for the former things"—and with this the need of our life work,—“have passed away.”

PENNSYLVANIA IN THE AMERICAN PHARMACEUTICAL ASSOCIATION.*

FRANKLIN M. APPLE, PHAR. D.

Pennsylvania Pharmacists and their families should be interested in the American Pharmaceutical Association for a great variety of reasons—sentimental as well as practical.

I will first direct your attention to the sentimental side of the query.

Are you aware of the fact that Pennsylvania played a most important role in the organization of the American Pharmaceutical Association?

Pennsylvania was the state in which it was organized in 1852, hence we can, with pardonable pride, point to it as, largely, a product of our beloved "Keystone State."

Of the list of sixty-one Presidents, Pennsylvania has supplied eleven of those chosen to the leadership: Prof. Daniel B. Smith in 1852, Chas. Ellis in 1857, Prof. Wm. Proctor, Jr., in 1862, Prof. Edw. Parrish in 1868, Chas. Bullock in 1876, Jas. T. Shinn in 1880, Chas. A. Heinitsh in 1882, A. B. Taylor in 1890,

*Read at the annual meeting of the Pennsylvania Pharmaceutical Association, held at Buena Vista Hotel, Buena Vista, Pa., June 23-25, 1914.

Prof. Jos. P. Remington in 1892, John T. Patton in 1900 and Jos. L. Lemberger in 1905.

As First Vice-President six pharmacists from our state have been honored by election to that office; as Second Vice-President two have served the Association, and as Third Vice-President three have been chosen.

For the important office of Treasurer, Mr. A. B. Taylor was selected to serve from 1852 to 1854.

The records show that, in the position of Corresponding Secretary, Pennsylvanians served almost continuously from 1852 to 1863.

As Recording Secretary, from 1853 to 1854, 1859 to 1862, and 1863 to 1865, pharmacists hailing from this state occupied the office.

When the offices of Corresponding Secretary and Recording Secretary were consolidated into the office of Permanent Secretary, our beloved Prof. John M. Maisch assumed the duties of the office and rendered efficient services until 1893, when Prof. J. P. Remington ("our Josie") took up the labors of his fellow professor for the ensuing year of the Association.

The very important and exacting office of Reporter on the progress of Pharmacy, was satisfactorily filled by Prof. H. Kraemer from 1892 to 1895.

As Chairman of the Council, the governing body of the Association between the times of meeting of the Association, Pennsylvania supplied Prof. Jos. P. Remington from 1880 to 1886 and from 1908 to 1909.

As Chairmen of the several Sections of the Association, the following have officiated as presiding officers: Prof. E. F. Cook, of the Section on Pharmacopœias and Formularies, organized in 1913; Mr. Jos. L. Lemberger, of the Historical Section, organized 1904; Mr. F. M. Apple, Prof. Louis Saalbach, and Mr. P. Henry Utech, of the Section on Practical Pharmacy and Dispensing, organized 1900; Prof. C. B. Lowe (2 terms), Mr. Jos. W. England (2 terms), Prof. Chas. H. LaWall and Mr. John C. Wallace of the Section on Education and Legislation, organized 1889; Prof. F. G. Ryan, Mr. Lyman Kebler, Mr. M. I. Wilbert and Prof. Chas. E. Vanderkleed of the Section on Scientific Papers, organized 1887, and the Section on Commercial Interests was under the guidance of the writer, in 1911. This Section was organized in 1887.

It will be observed that the first President, first Treasurer, first Corresponding Secretary and the second Recording Secretary were recruited from the pharmacists residing in Pennsylvania, and that we have always supplied a large number of active workers to assist in guiding the destinies of the Association—amongst whom we are very highly pleased to note the name of "The Father of American Pharmacy," Prof. Wm. Procter, Jr. To the untiring efforts, deep thought and helpful suggestions of our Jos. W. England, to a large degree, can be attributed the inception of one of the greatest assets of the Association—"The Journal of the American Pharmaceutical Association."

With such a record of valiant service rendered by the pharmacists and chemists claiming this state as their home at the time of their term of office, should it not appeal to the pride of every Pennsylvania pharmacist eligible for membership in the American Pharmaceutical Association, and arouse in them a strong desire to be numbered among the members of such an organization?

Laying aside the sentimental side of the question, we will now approach it from the practical side, and inspect the claims of the Association upon those eligible for membership.

It will be observed that the first Section organized by the Association was that of Commercial Interests, indicating that commercial problems and customs were not ignored or tabooed by the fore-fathers. In fact the original Constitution and By-laws of the Association demonstrate that unsatisfactory commercial condition was one of the prime causes leading to its organization. A careful study of its archives, proves that the materialistic side of pharmacy was never lost sight of, and continued efforts were made to remedy commercial customs that were the cause for complaint by many of the pharmacists of the past six decades of years.

It has been truly said to be a scientific and professional association, as a perusal of the minutes of its Scientific Section will prove; but it did not neglect or frown upon commercial questions as it has been repeatedly but unjustly, accused of doing. When a proposed remedy for an evil custom,—one that it was thought would stand the test of the courts,—was presented for consideration, it received careful attention by the *entire* membership in its annual sessions, not excluding those members supposed to be interested solely in scientific investigations.

The continued existence of pharmacy, as a learned profession, is due to the Association's fostering influence, more than to any other known agency; hence your ability to practice pharmacy, as a distinct and respected vocation, must be credited to this organization.

Since the organization of the Section on Practical Pharmacy and Dispensing a wonderfully rich reservoir of knowledge has been tapped, from which inestimable benefits have flowed to all practical pharmacists; in the majority of cases its beneficiaries being ignorant of the source of the helpful influences.

Legislation has received its due attention, and many of the legal rights and privileges you enjoy, emanated from the deliberations of its members.

For years, it has been customary for the wives and families of some of the members, to accompany their husbands and fathers to the annual gatherings, thereby making priceless acquaintances and friendships. A few years ago, it was decided to establish a Women's Section, to be officered and managed completely by the ladies, thereby affording them an opportunity to satisfy their desires to advance the interests of their sisters, who have taken up pharmacy as a life work, and to render whatsoever assistance lay in their power in aid of the general interest of the profession and business of pharmacy; hence it should be perfectly clear to all that provision has been made for the members of both sexes to labor together for the benefit of pharmacy, and of pharmacists and their families.

Under such conditions does it not appeal to you, ladies, that you should urge your husbands, brothers and fathers to become enrolled as active members thereof, and thereby, automatically, to make yourselves eligible to join in the activities of the Association?

If one is *truly* interested in an association or effort, he or she will become active in its behalf and be a missionary for it.

Do you not feel that *you* should become *truly* interested in the American Pharmaceutical Association, and experience the joys and benefits of membership therein?

We extend to you an earnest appeal to join our ranks and assure you we will accord you a warm welcome when we can grasp your hands as fellow members.

"Never put off until tomorrow what should be done to-day"; hence decide to accept the invitation and join us in our efforts to uplift American Pharmacy.

ORGANO-THERAPY FOR PHARMACISTS.*

BY JOHN ZIEG, M. D.

I will discuss only those biological products which are derived from the adrenal, thyroid, thymus, pituitary and ovarian glands, as these are the most important and most used, and their therapeutic value is quite well established. Frankly, reliable information, of practical value to the dispensing pharmacist, is obtainable only from those who prepare these products. To those who become interested, I would suggest that they obtain the printed literature and read the details.

Let me impress upon you,—

(1) That these remedies as a class have already won a place among reliable therapeutic agents.

(2) Their physiological action is to a great extent known even now, i. e., that action which can be recognized clinically, after the administration of sufficient dose, for a long enough period—this in distinction to their action in the normal body, where the activity of these glands is strongly interrelated, to preserve an equilibrium of paramount importance in the preservation of health.

(3) Very remarkable results have been consistently obtained in the regular clinical use of these agents and that, too, in conditions resistant to other treatment. For example, of adrenalin—its powerful local astringent and hemostatic action—its rapid powerful internal action as a cardiac stimulant, and its equally decisive and reliable action of relieving the paroxysms of asthma.

Then again, of pituitrin, its remarkable action on non-striped muscular tissue, which makes it a marvelous aid in overcoming uterine inertia in labor, a heart-tonic of merit and a remedy of worth in many conditions of muscular atonicity. Then, in the use of thyroid extract or thyroprotein, we find wonderful results, in conditions due to deficient function of the thyroid gland. I might mention more, but these should suffice to arouse the interest of the pharmacist and stimulate in him a desire to learn more of the details of their manufacture and use.

Lastly, these remedies should be used only under the direction of a qualified physician.

Preparation.—In manipulating material so unstable as glandular tissue from the animal body, with a view to preserve it and the active substance it contains, great care and skill must be exercised. A thorough knowledge of the structure both gross and microscopical, together with all the information available on the phy-

*Read before the San Francisco Branch, June 9, 1914.

siology of the gland, must be taken into consideration. In the case of the above mentioned glands, the original preparation consisted of the dried substance of the fresh gland, which was previously freed of all extraneous tissue—then ground and put into capsules. At this time considerable advance has been made over the process of simple desiccation of the recent gland.

Care in obtaining fresh material:—This includes the inspection of the animal for diseased condition—no material being taken from animals not otherwise fitted for consumption for food—further the glandular tissue, itself, is inspected for abnormal conditions, since it is quite possible to obtain glands that are far from normal from an animal presenting no condition requiring its condemnation for general food purposes.

Care of fresh material before preparation:—It is needless to say no time is lost in getting the preparation under way, but in the short interval which elapses, from the time the gland is removed from the animal, until the process of preparing it is begun, adequate refrigeration and protection from contamination and infection is provided.

Manipulation of the fresh material:—This includes the thorough removal of extraneous tissue, like fat and connective tissue and the separation of such portions of the gland-tissue proper, which is known to have no value in the preparation of the particular product in hand, i. e., in the case of pituitrin, only the posterior lobe is used, and it must be very carefully separated from the anterior lobe.

Scarcity of fresh material:—From the foregoing it is evident that unlimited supplies are not available, indeed the supply rarely equals the demand, as in the case of pituitrin and corpora lutea,—in the preparation of which only a small part of the whole gland is used,—the problem of obtaining sufficient supplies becomes, at times difficult.

A careful consideration of the foregoing points will give some idea of the care, skill and equipment entering into the production of these therapeutic agents, and the cost attending the same.

LISTED PREPARATIONS.

Thyroid gland:—Desiccated gland—U. S. P., physiologically tested, assayed to contain not less than 0.2 percent iodine, in capsules or tablets, for internal administration.

Thyroprotein (Beebe)—concentrated extract, containing active principle, physiologically tested, assayed to contain not less than 0.33 percent iodine, in tablets containing 1/50, 1/25, 1/10 gr., for internal administration, in glaseptic ampoules containing 1/50 grain, for hypodermic use.

Adrenal gland:—Desiccated gland—U. S. P., physiologically tested, in capsules or tablets. Adrenalin, the active principle—in powder form or in hypodermic tablets, in solution, in vials or 1 cc. ampoules.

Thymus gland:—Desiccated gland—in capsule or tablets for internal administration.

Pituitary gland:—Pituitrin—active principle, in solution, standardized physiologically on the basis of its blood pressure-raising property, in 1 cc. ampoules for hypodermic use.

Ovarian gland:—Corpora Lutea, desiccated—the dried substance of the yellow glandular material, only—the remainder of the gland being discarded.

Because adrenalin is the oldest, has well established worth, and is much used and frequently dispensed, I shall present some of the most important points in relation to it. There is a good deal of sophistry about deterioration of products like adrenalin. It should be generally understood, that it is absolutely impossible to prevent the ultimate deterioration which takes place in adrenalin and other suprarenal products. The change in a product like adrenalin is indicated by a pink color which grows increasingly more intense as deterioration develops. In the early stages, no appreciable loss of strength results, and it is not until the product actually turns brown, and begins to precipitate, that it loses much of its efficiency. Now this change of color, can be prevented by the use of a bleaching-agent like sodium sulphite, but the deterioration goes on just the same—the loss of strength is not prevented—it is simply concealed. The pharmacist who keeps his stock bottle (the opened-one especially) away from heat and alkaline reagents, and in such a way that dust, cotton or organic matter cannot gain access, will have a minimum of deterioration and will be able to dispense this product with entire satisfaction to his trade and himself.

Adrenalin in the presence of alkalies, even in high dilution, undergoes rapid deterioration, and when so prescribed by a physician, it is eminently proper that he be told of this change. A much disseminated error is, that adrenalin cannot be sterilized by heat. This became current about the time synthetic suprarenin was issued. The following tests bring out the facts regarding this point:

1. Ten cc. of 1:1000 solution, in a test tube closed with absorbent cotton, were immersed in boiling water for 15 minutes. At the end of this time the loss by exaporation was compensated, by the addition of distilled water,—careful testing showing the solution to be full 100 percent. The remaining solution was again immersed in the boiling water for a second period of 15 minutes, and the loss again corrected,—careful testing showed the product to be still 100 percent. This was repeated a third time and the adrenalin again gave a full 100 percent strength.

2. Twenty-five cc. of the adrenalin solution in a tightly-stoppered vial were immersed in boiling water for 15 minutes. This was repeated twice, and after each period of 15 minutes careful tests of strength were made. After the three heatings the adrenalin tested full 100 percent.

3. A very severe test—20 cc. in a small open-mouthed flask were boiled for five minutes. At the end of this time about 60 percent of the original solution had been evaporated but the volume was restored by the addition of distilled water and the solution then tested. This was repeated twice and tested after each addition. After the second boiling the adrenalin tested 100 percent and 90 percent after the third. This third test is a very severe one and is one which no careful pharmacist would resort to in the sterilization of his products, as such treatment would decompose ordinary alkaloidal solutions, such as morphine sulphate or atropine salts.

It will be seen from the above, that sterilization by the first two methods, are

quite practical, for periods from 15 to 30 minutes, or even longer, without impairing the activity of adrenalin, and that the pharmacist is able to dispense freshly sterilized solutions of this agent, when called upon to do so. One point in this connection should be noted,—it is advisable to sterilize only the quantity needed for immediate use.

THE GENERAL USE OF NEW SYNTHETICS.*

FRANKLIN M. APPLE, PHAR. D.

A careful search for the causes that lead to self medication by the laity with the newer synthetic remedies reveals the fact that a number of agencies are responsible for the practice.

The prime offenders in this respect are the manufacturers of the products termed patent chemicals, who ingeniously invent and apply to their goods easily pronounced names, which are not difficult for the consumers of their products to remember.

Ostensibly these euphonious names are adopted for the benefit of the medical practitioners, but their true object is to catch the eye and ear of the patient, who may soon dispense with the services of his physician, when he imagines he needs the chemical previously prescribed by his medical adviser; for it is not very difficult for a party of average intelligence to read a prescription for such a medicament, if it is clearly written by the prescriber.

If the physician announces his diagnosis of the case to his patient when handing him a prescription legibly written for one of these synthetic products, it is quite probable that the patient will associate the disease and the remedy together, with the result that he decides at a later date, when suffering with similar symptoms, that he need not consult his medical adviser, and he proceeds to medicate himself without the necessity of paying a fee for advice to take the formerly used chemical.

What has been stated concerning the possibilities of the patient associating the diagnosis with the remedy becomes an assured fact when the medical men prescribe verbally for the patient—whether it be by telephone or otherwise,—adding thereto explicit directions for the patient's benefit, in order to avoid writing a prescription, which is a very suicidal policy, indeed, for physicians to follow.

Experience has proven that the cause for some of this practice can be traced to the doors of the trained nurse, who, through a sense of friendly interest or vanity, usurps the role of the physician, and, in some instances, goes much farther in her support of the remedy by extolling its merits most heartily.

Those of our calling are, at times, found to be guilty of the same practices that some trained nurses follow—undoubtedly actuated by the same motives—with the result that the patients are unconsciously taught self-medication.

The patient becoming possessed of a (to him) wonderful new remedy proceeds

*Read at the annual meeting of the Pennsylvania Pharmaceutical Association, held at Buena Vista Hotel, Buena Vista, Pa., June 23-25, 1914.

to take a friendly interest in his fellowmen, who appear to be afflicted with a malady similar to his previous ailment, with the result that he is a free medical adviser and a good press agent for the manufacturer.

To sum up the entire situation I would state that the causes for the use of the newer synthetic remedies by the laity is a studied effort upon the part of the manufacturers thereof to encourage self-medication by the public for their financial gain; and *careless practices* by some nurses, physicians and pharmacists, which lead to the same end—self-medication by the public.

ALCOHOL AS A FOOD.

The influence of alcohol upon metabolism, as the chemical changes that occur in living matter are called, having now passed from the field of speculation and controversy into the realm of ascertained fact, there is no longer any justification in denying to alcohol the right to be regarded as a food. The chief property upon which this claim is based is that of partially paralyzing the living cell, thereby inhibiting the breaking down of the particles of fat or carbohydrate with which it is surrounded. The living cell normally preys upon these and proteid particles, and by breaking them down is enabled to make good the wastage of tissue resulting from its own combustion.

Alcohol is in this respect a "fat-saver," though it is itself consumed in the process, yielding heat and energy to the body.

Apart from their alcoholic contents, however, many spirits possess great value at certain times by reason of their stimulating effect upon the heart, brain and other vital centres. Preeminent in this respect is the finest old liquor brandy, which owes its peculiar properties to the presence of small quantities of highly complex volatile ethers formed from the acids and alcohols present during the period of maturing.

Owing to its property of dissolving many organic substances, alcohol is of great value as an aid to digestion, and as a stimulant and restorer of circulation it occupies an unrivaled position. Nevertheless the use of alcohol must be regulated with a nice discrimination, for its effects are not always what they seem. It is unwise, for instance, to take alcohol before going out into the cold, for by so doing the blood will be driven into the surface blood vessels and capillaries, and through their subsequent dilation an excessive amount of heat will be radiated from the body just when it is most required. It is right and proper, however, to take alcohol on returning from the cold, for it will then promote the circulation throughout the body of all the blood which contact with the outer cold has driven from the surface and the extremities away into the internal viscera.

It is well to bear in mind that alcohol does not keep one warm. On the contrary, it lets out one's heat.—*London Times*.

American Pharmaceutical Association

Organized 1851. Incorporated 1888.

GEORGE M. BERINGER, PRESIDENT

501 FEDERAL STREET, CAMDEN, N. J.

Dear Fellow Member:

The time is rapidly approaching for the Sixty-second Annual Meeting of the American Pharmaceutical Association. Detroit is famous as a convention city; renowned alike for its beauty and the hospitality of its citizens. The advance news is that the local committee have prepared to make our stay full of enjoyment and that the various Sections have arranged programs replete with matters of interest and profit.

We believe that this meeting, August 24th to 29th, will be a notable event in our history and will be the largest gathering of representative pharmacists ever held in this country.

The officers extend an invitation to you to come and enjoy to the fullest extent the pleasures in store. May we have your presence and co-operation? If you have never attended a meeting of the Association, attend this year and get imbued with the prevailing spirit and enthusiasm. If you have been attending, you will understand what an influence and benefit to each member is a meeting of the Association that stands for the welfare of all concerned in pharmacy. Goethe has well said: "There is no teaching to compare with what we derive from intercourse with others."

To the former presidents, I extend a special invitation. It is the hope to have present at the opening session all of the living former presidents.

Come and, if possible, bring along a new member to help the good work of the Membership Committee. There is going to be much of interest and ties of friendship and good fellowship will be renewed and strengthened.

This invitation, of course, includes the wives and daughters and lady members of the Association, as without the presence of the fair sex there could be no full enjoyment of the occasion.

The American Pharmaceutical Association is the exponent of all that tends to the welfare of pharmacy. Its aim is true, ethical and progressive pharmacy. Its activities are extending along ever increasing avenues of usefulness. The president will welcome suggestions from any member for improvement in methods or for additional lines of activity beneficial to pharmacists.

Looking forward to the pleasure of greeting you at Detroit on August 24th, I am

Yours fraternally,

GEORGE M. BERINGER, President.

CAMDEN, N. J., July 10, 1914.

Editorial

JAMES H. BEAL, Editor.....Scio, Ohio
 ERNEST C. MARSHALL, Acting Editor.....63 Clinton Building, Columbus, Ohio

TIME TO HALT.

WE would especially call the attention of every member of the A. Ph. A., and, thru them, that of every member of the profession, to the wise, brave and strong words of Dr. Beal which are contained in this issue under the caption, "Legislative Problems in Pharmacy."

Every sentence of this article should be studied by the druggists of this country, particularly by those who are engaged in endeavoring to shape the legislation of the nation and its several states.

The country seems almost to have gone apothecary-law-mad in its efforts to restrain imagined evils,—or if not imagined evils, at least grossly exaggerated ones, and, as Dr. Beal so well says, the drug-trade seems to have been a target for restrictive legislation, as if they, and they alone, were the only evil-doers; the panderers to all the morbid and depraved appetites of the country.

The fear, that even simple remonstrance to the most vicious legislation of this character may cause the objectors to unwise and burdensome laws to be classed as wrong-doers, has often prevented druggists from objecting to such laws, and, in consequence, restriction upon restriction has been piled, like Pelion on Ossa, upon the already over-burdened backs of the members of our profession.

Such pusillanimity has encouraged these persistent pests who are engaged in the attempt of reforming the world according to their light, and deceived by the apparent plea of "Guilty" by the druggists and their lack of resentment, their not "fighting-back"; their "appetite grows with feeding" and they seek to restrict more and more our sales, until, unless they are checked, they will require a prescription to be shown for even sales of postage-stamps or the use of the telephone. And it is not alone these men who are silly in their ideas. Some of our own are as bad. Why should a person be required to have a prescription to buy seven and a half grains of corrosive sublimate of a druggist, when they can buy a pound without such prescription of any general dealer in chemicals or even of the village grocery-store?

Not only are these restrictions burdensome to the practice of pharmacy, but they oppose its respectable exercise. It is not alone the "yellow" journals which hold the drug-trade up to odium, but respectable journals lend their columns to disseminate the same reprehensible views. Recently one of these, with the largest circulation in the country, published an article entitled, "How Kansas Boarded the Water-wagon," which contained such slurring references as the "tipple of

drug-stores," the "drug-store joint," "liquor sold behind imitation prescription-cases," etc., etc.

Far beyond the exaggerated statements of the article in representing that no liquor is now sold in Kansas, in its importance to our profession is the demagogic representation that the drug-stores of Kansas were the persistent violators of the laws. Such insinuations are mean and despicable. As well might we hold up all writers for the press as drunkards because there are a few conspicuous examples in that class.

There are Police Gazettes in Journalism, but we should be unfair and unjust to class the Saturday Evening Post as one of that class of periodicals, and it is also unfair and unjust for that journal to allow its columns to disseminate the idea that the practice of the Profession of Pharmacy is connected with pandering to vice and the demoralization of the community.

It is time that we showed resentment against these injurious and false misrepresentations, especially when further quiet submission to them is but encouragement to more animadversion and the imposition of more vexatious burdens and also when a patient sufferance is interpreted as conscious guilt.

CONVENTION DISPATCH OF BUSINESS.

THE most annoying and delaying interference with the prompt and agreeable dispatch of business at our Annual Meeting, is said by many people who have observed matters carefully at previous conventions, to be the seeming utter disregard of the Chairmen of the Sections, to the time-schedule, arranged with care by the Local Committee, from which there results confusion, delay, and chaos in the dispatch of the program. For no matter how well-conceived and arranged such a program may be, or how zealously the Local Secretary and his Committee may have been in the planning of details, and in their work for the proper conduct of the Convention, these conditions must appear, without strict attention to the schedules arranged for the conduct of the meetings.

Think for a moment of the confusion that would take place in a railroad system if the conductors of trains paid no attention to the time-tables, and each man took his train from the station at any time he pleased, or when his passengers thought proper, and the conception of the results which would ensue from that course of action, will give one an idea of the result of a disregard of their time-schedules by the conductors, or Chairmen of Sections.

It has been often observed that members have come to Section Meetings at the times appointed for them, and observing no signs of any meeting, have gone away and not returned, either thinking the meeting postponed, or that it was being held elsewhere, and that enough of these members have so gone away as would have made an audience worthy of the Section.

At the Los Angeles meeting, the Chairman of the Section of Practical Pharmacy and Dispensing, announced that his meeting would begin promptly at the time appointed, if not a member was present, with the result that the meeting was begun on schedule time with a large attendance, and was one of the most successful sessions held at the Convention.

If the rule should be adopted at the Detroit Convention, that the Chairman's gavel, falling to open the Section session, should drop at the precise minute appointed for the opening of that session, more would be done for proper dispatch of business than gallons of printers' ink used in discussing the number and name of the various sections; but without the adoption of this simple plan, no amount of work or change of method will be affective in bringing about a better result in the dispatch of business. The Local Committee requests the announcement that it earnestly requests the Chairmen of Sections to be promptly on hand to call their sessions to order at the times appointed, and announces that the first meeting to be called at the Convention, will be that of the Chairmen of Sections to consider this first and most important point of Fidelity to the Time-schedule.

SUPERSTITION IN MEDICINE.

From the most ancient times we read that more or less superstition was rife among the peoples of the earth; a belief in the possession of virtues in things unusual to possess them, and the more unusual or strange such belief, the more firm was the faith of those who attributed value to drugs or charms. Herbs should be gathered in the light or the dark of the moon, or with the repetition of cabalistic words at the time of their gathering, without which the herbs were of no remedial value. Strange things were used in pharmacy under the influence of this belief. Schenklius, Mizaldus and Rhasis commended, for the cure of mental troubles, "an old cock, a ram's head or a wolf's heart." A belief in the potency of gems to ward off or to cure disease was common; Paracelsus was a believer in the efficacy of the ruby, either powdered and taken, or worn in a ring, and Renodæus said that, "Precious stones defend us from enchantment, cure our diseases, drive away griefs and exhilarate the mind." Encilius commends the ruby as a remedy against sorrow, and a restorer of reason. Albertus wrote in praise of a stone called "Chelidonium" which was found sometimes in the belly of the swallow, and said it was a positive cure for lunacy. Lemnius praised the carbuncle and coral as possessing mystic power "to drive away fear and devils, overcome sorrow and repress troublesome dreams." One of the approved medicines of the ancient times, was "a ram's head, that never meddled with a ewe, cut off at a blow, and the horns only take away, boil it well, skin and wool together; after it is well sod, take out the brains, and put these spices to it, cinnamon, ginger, nutmeg, mace, clove, of each a half oz. Mingle the powder of these spices with it, and heat them in a platter upon a chafing-dish of coals together, stirring them well, that they do not burn; take heed that they be not too much dried or drier than a calf's brains ready to be eaten."

Amulets were much approved by Mizaldus, Porta, Albertus, and others. The Edinburgh Pharmacopœia of 1790 has lingering traces of these strange beliefs in its inclusion of Crab's Claws and Eyes, Millepedæ and their preparation as a conserve. But after this period there does not appear much of the superstition in the pharmaceutical works of authority.

In all times there have been these beliefs in the occult and mysterious influences for good and for evil upon the destinies of man.

In Ben Jonson we read:

Subtle,—And

Beneath your threshold bury me a loadstone
To draw in the gallants that wear spurs; the rest
They'll seem to follow.

This, the advice of the alchemist to the credulous Druggier, who comes for advice in regard to the equipment of his store, gives evidence of a prevalent belief in spells and charms in determining the affairs of life in those days, and a like belief has been maintained since the earliest days of recorded history.

Horace testifies, in the Fifth Ode of Book I, that it was customary to offer a sailor's garments to the powerful God of the sea:

*"Suspendisse impotenti
Vestimenta maris deo."*

And it is said that the walls of the Temple of Æsculapius were covered with tablets and inscriptions erected by those who thought their sacrifices to him had cured their ills. We smile perhaps at the credulity of these ancient peoples, but not long since, at a dinner-party at which there were present some of the men most eminent in the country,—those prominent in politics, literature and in journalism,—the subject of belief in things occult being broached, there was not one present who could deny their absolute unbelief in all the superstitions which are generally thought to belong to the province of the childish or uneducated. One man, and he a distinguished commentator on Darwin and Spencer, firmly avowed that he had actually seen the personal devil and gave a harrowing description of his appearance. One said he would never be a member of a dinner-party at which he made the thirteenth person; another never would begin an enterprise on Friday, and when it was the thirteenth of the month there was "nuthin doin'" for him. Thackery believed firmly in "luck" and Napoleon is said by Bourrienne to have believed in "his star."

How many of us "knock wood" when speaking favorably of our health or prospects; like to see the new moon over our right shoulder, or like the man in Hoyt's play are "not superstitious, but don't like to walk under a ladder?" How many of us put on our right shoe first; dislike to meet a funeral on our way to important business, or sneeze without ejaculating a prayer? A number of years ago, the question of launching a battleship on Friday was made the subject of discussion in the navy department of this great nation. And so it goes, and it must be feared that some of our present-day ideas are not far removed from those days of Horace and of Jonson. We are prone to look upon the other man as being weak and childish in his belief, while we at the same time may be carrying a horse-chestnut to keep away the rheumatism, or wearing a stocking wrong-side out for fear of changing our luck. As Carlyle says, "My doxy is orthodoxy, your doxy is heterodoxy."

It is of course useless to argue against these things,—as well try to argue a Christian Scientist out of his belief that there is no pain, even when an exposed nerve is causing him to groan in anguish.

"Such fools these mortals be."

Doubtless the reason, to some extent at least, for this belief in spells and

amulets and charms, is that men realize their insufficiency to cope with the vast powers of nature, and also their ignorance of what is in store for them in the Great Beyond. He is thus led to rely upon those things which his sober senses should assure him have no more power to influence his life, than the "Mumbo Jumbo" of an African tribe has over the destinies of those who bow before it in humble adoration.

Drugger hoped by the loadstone to draw in patrons, not relying upon the fact that in himself should be the magnetism to draw to him all who came within the circle of his influence. It is a misfortune for a man not to realize and to depend upon this positive fact. Let the young druggist, in the founding of his store, place for its corner-stone the desire to serve his patrons honestly and sincerely. Let him inscribe upon it the resolve to sturdily resist the sordid commercialization of his business; let him earnestly strive to maintain the high professional standards of the most honorable and best profession in the world,—one that has numbered in its ranks the truest and noblest of mankind, and to him will be gathered not only the monetary return which always follows such ambitions and such service, but that lasting reward which comes to every man who does his duty well and faithfully, the approval of his conscience and the knowledge that, in so far as lay in his power, he has advanced the profession he has chosen for his life-work.

TO EVERY MEMBER—FROM THE LOCAL COMMITTEE.

"Of course" you are coming to the A. Ph. A. Convention, which will be held in Detroit the week of August 24, 1914.

The Committee of Arrangements have planned a most elaborate program for your entertainment, the principal features of which will be a Reception and Grand Ball on Monday evening, August 24, the music for which occasion will be furnished by a famous Berlin orchestra of sixteen pieces. Other attractive features will be a theatre party, dinner and card parties, shopping expeditions, and a boat ride to Bob-Lo Park and dinner for the ladies, and a smoker and vaudeville performance for the men, and for all the members a day-light ride to the "Flats," the "Venice of America," on the palatial steamer Britannia, and a four-hour ride thru our parks and boulevards. All this for your pleasure and entertainment.

The same care has been exercised in arranging the business program, so that the various sections will not conflict, and you can attend any or all of them as you desire; there will be no tedious waits as the gavel will fall at the time appointed for the meetings. This meeting will be an innovation to you, so just throw a few things in your grip, and come along, and bring the ladies with you, as every preparation is being made for their care and comfort.

DETROIT EXECUTIVE COMMITTEE.

PLAN OF A. PH. A. HEADQUARTER'S ENVIRONMENT AT DETROIT.

Duplicate small figures refer to City Ticket offices.

FACTS OF INTEREST ABOUT DETROIT, THE CONVENTION CITY.

It covers an area of 41.76 square miles, has twenty-nine public parks, among them being Belle Isle, the most beautiful island used for a public park in the world; and its handsome boulevard, which encircles the city, is said to be the finest in the country.

It is the first city in the world in pharmaceutical-manufacturing, automobile-production, pin-manufacturing, wire cloth, and stove-making, and several other important lines of industry.

More than 20,000 people are employed in the chemical and drug-industries of the city, the larger firms being, Parke, Davis & Co., F. F. Ingram & Co., Frederick Stearns & Co., F. A. Thompson & Co., and the Nelson, Baker Co., which firms are to be the generous hosts of the Association in the entertainment features of the Convention,—and at whose establishments visitors will be cordially welcomed.

The Local Secretary urges the members to make reservation of their accommodations in Detroit as soon as possible, as the city is a popular resort at the time of the Convention and much better service and accommodation will be assured to members by securing early reservation of their rooms. It is also requested that those who reserve rooms bring the letters in relation thereto with them in order to save any misunderstandings.

One of the most popular features of Detroit is the fact that it is surrounded by so many beautiful and interesting spots, places that can be reached by boats and trolleys, away in the morning and back in the evening. Some place new to go every day and all different, is the way it has been expressed a million times.

WHERE TO GO.

Amherstburg, a quaint old Canadian town near mouth of Detroit River, overlooking Lake Erie; reached by the D. & W. boats and electric cars from Windsor; also good auto roads.

Ann Arbor, the home of the University of Michigan, forty miles from Detroit; reached by inter-urban cars and Michigan Central. Good auto roads.

Belle Isle is known the world over for its beauty. Steamer every ten minutes from the foot of Woodward avenue, ten cents for round trip or ride on steamer all day for ten cents; also Jefferson avenue car line to Boulevard and thence automobile bus line operated by the City of Detroit; automobile fare six cents round trip.

Bob-Lo, popular and attractive island in Detroit River, reached by D. & W. steamers. Athletic field, bathing, boating, dancing and modern cafe; no liquors; 35 cents round trip.

Cedar Point, on Lake Erie, noted for its bathing and numerous summer attractions. Steamers Kirby and Put-in-Bay from Detroit; \$1.25 round trip.

Chatham, Ontario; superb boat ride from Detroit up the beautiful and picturesque Thames River.

Detroit Art Museum, Jefferson avenue, open every day in year to public; fine pictures, sculptor works, art collections of various kinds including some of the finest foreign productions on this continent. Value many millions of dollars. FREE.

Hammond Building
Ford Building

Penobscot Building

City Hall

Dime Savings Bank Building

Free Press Building
(Background)

The Flats, called the "Venice of America," about 30 miles from Detroit, and the finest water ride in the world; paradise for fishermen; reached thrice daily by White Star Line boats; fine motor-boat trip. Round trip rates 60 cents.

Fort Wayne, United States army post, located on river just below Detroit; reached by city cars.

Gladwin Park, fronts Jefferson avenue, four miles east of Woodward avenue.

Grand Boulevard, nearly twelve miles long, encircling central portion of city, and crossed by all the principal avenues. Excellent automobile trips around the city.

Grosse Pointe, the fine summer residence district of Detroit, should not be missed. Reached by Jefferson-Grosse Pointe cars and elegant auto driveway.

Kingsville, an Ontario resort; place of note, is on Lake Erie and can be reached by the W. E. & L. S. electric line from Windsor, giving strangers a beautiful ride through Canada.

Lakeside Inn is near Mt. Clemens, looking over Lake St. Clair, and can be reached by trolley; automobile ride being fine and auto boat route the best out of Detroit. Golf links and other amusements.

Mount Clemens, year round health and pleasure resort, just twenty miles from Detroit and near Lake St. Clair; reached by two trolley lines of D. U. R. and Grand Trunk railroad. Good auto roads.

Palmer Park is one of the finest show places of Detroit. Reached by Woodward avenue cars marked Log Cabin.

Pontiac, and the Oakland county lake region, finest fishing in Michigan. Fine lakes. Two hours from Detroit by two trolley lines. Fine auto roads.

Port Huron, overlooking Lake Huron, five hours from Detroit; White Star Line and D. & C. steamers; Grand Trunk and D. U. R. inter-urban.

Put-in-Bay, historic and beautiful island located in Lake Erie; fine bass fishing, bathing beach, boating, etc. Reached by steamer Frank E. Kirby and steamer Put-in-Bay. One hundred and twenty miles; round trip 60 cents.

River Riding is one of the summer pastimes at Detroit, the D. & W. Ferry Company operating the finest fleet of excursion steamers on fresh water in the world; hours and hours, up and down the river, just enjoying life, at a cost that is not greater than riding in a street car in your own city.

Stag Island, first stop this side of Port Huron. Good fishing, bathing, and excellent hotels and cottages. Ideal island for outing.

Sugar Island, at mouth of Detroit River, overlooking Lake Erie; reached by White Star Line steamers from Detroit and Toledo. Fine picnic park, bathing and numerous summer attractions; 35 cents round trip.

Tashmoo Park, a beautiful summer spot at the Flats, reached only by White Star Line steamers; athletic field, picnic grounds, boating and fishing; 60 cents round trip.

THE SCIENTIFIC SECTION

A Partial List of the Papers to be Presented at Detroit.

Glycerite of Bismuth, by W. L. Scoville.

The Necessity of a Method of Estimating the Intrinsic Value or Essential Qualities of Coffee, by L. E. Sayre.

Third Alkaloid from Gelsemium, by A. E. Stevenson and L. E. Sayre.

Examination of *Calycanthus Floridus* for Alkaloids, by E. R. Miller and H. W. Brooks.

Stillingia Sylvatica, by E. R. Miller, R. L. Brooks and C. P. Rutledge.

The Analysis of Emulsions, by C. H. LaWall and L. Forman.

The Analysis of Some Additional Coffee Products and Coffee Substitutes by the Method Recently Proposed for the Detection of Chicory in Decoctions of Chicory and Coffee, by C. H. LaWall and L. Forman.

The Determination of Glycerin in Tablets and Confections, by L. Forman.

On Physiological Assaying, by F. W. Connolly.

New Science of Immunology, by F. E. Stewart.

A Photographic Presentation of Some Phases of Lloyd's Reagent, by J. U. & J. T. Lloyd.

Official and Other Tinctures, by M. I. Wilbert.

The Differentiation of Senna and Henna Leaves, by W. R. White.

The Quality of Morphine Nitrate and Morphine Acetate, by H. Engelhardt and O. E. Winters.

The Estimation of Elementary Phosphorus, by H. Engelhardt and O. E. Winters.
Estimation of Calomel, by R. I. Grantham.
Laboratory Notes, C. E. Vanderkleed and G. E. E'we.

Assay of Opium, A. R. L. Dohme.

The Structural Variation of Allspice, by Wm. Mansfield.

Notes on a Glycerin Substitute, by Jos. Feil.

Uniformity in Dosage of Radium Emanation, by W. J. Schieffelin.

Glands of Internal Secretion and Their Importance as Therapeutic Agents, by C. P. McCord.

The Pharmacy of Adrenalin, by C. P. Beckwith.

Cannabis Sativa: Is the Medicinal Value

Found Only in the Indian-grown Drug? by H. O. Hamilton.

What is the Best End-point of the Reaction in the Frog-heart Method of Digitalis Assay? by H. C. Hamilton and L. W. Powe.

The Analysis of Cigarettes, Cigars and Tobacco, and the Use of Lloyd's Reagent in the Determination of Nicotine, by Azor Thurston.

A Simple Form of Nitrometer for the Assay of Spirit of Nitrous Ether, by T. J. Bradley.

Notes on the Assay of Hydrastis and of the Fluidextract of Hydrastis, by H. W. Jones.

Report of the Committee on the Quality of Medicinal Products, by E. L. Patch, Ch'm.

The Pharmacognosy of the Medicinal *Rhamnus Barks*, by E. N. Gathercoal.

SECTION ON PHARMACOPŒIAS AND FORMULARIES.

This Section has always had as feature of its first session, after the Chairman's address, the reading of the reports from the Chairman of the U. S. Pharmacopœia Revision Committee; the Chairman of the American Pharmaceutical Association Committee on the U. S. Pharmacopœia; the Chairman of the National Formulary Revision Committee; the Chairman of the Committee on Unofficial Standards, and the Chairman of the Recipe Committee.

Dr. Bernard Fantus promises to discuss the Pharmacopœia as a help to the physician.

Mr. Beringer will present a review of the new Homeopathic Pharmacopœia.

Mr. Wilbert will give a review of the Norwegian Pharmacopœia, and possibly a review of the new British Pharmacopœia will be at hand.

The second session will be devoted to an exhibition of a large number of the new or modified U. S. P. IX and N. F. IV preparations, together with an exhibit by Professor Newcomb of the University of Minnesota of the crude drugs of both books. The preparations of the Exhibit have been made by a number of the members of the Association, each preparing six samples; the proposed formulas for the new editions being followed minutely in every case. Those who have prepared these specimens will report upon the merit of the processes. About fifty mem-

bers have taken part in the preparations of this display.

This session should prove of interest to the members of the Association and should materially assist the members of the two Revision Committees at this time in the Revision; the final manuscript for both books being in course of preparation.

E. FULLERTON COOK, Chairman.

SECTION ON PRACTICAL PHARMACY AND DISPENSING.

Ferdinand W. Nitardy, Ph. C., the Chairman of the Section on Practical Pharmacy and Dispensing, has sent out the following list of suggestions for subjects of papers to be read before that Section at Detroit, and requests that answers or comments thereupon be sent to him in time to be included in the program of the Section:—

1. R. Creosote1 dr.
Compound Syrup of Hypophosphites8 oz.
Cod Liver Oil.....8 oz.
Mix..... Sig.
How would you fill it? Why?
2. What do you think of using a specially shaped bottle for dispensing poisonous or dangerous preparations? Where would you draw the line as to what should and what should not be dispensed in these kind of bottles?
3. What is the best container for dispensing ointments on prescriptions?
4. Does the ordinary shop label as supplied by most label houses give intelligent directions for use, proper and available antidotes in case of poisons, and such other information as is desirable? Are abbreviations desirable? Do you consider a bottle of spirit of camphor put out under a label reading "Spts. Camphor" any reflection on the pharmacist's knowledge?
5. How would you advertise your prescription department?
6. What constitutes good prescription service?
7. What utensils and apparatus do you consider necessary for the prescription department of the average pharmacy? What further equipment would be desirable?
8. How far may the druggist go in marketing his own preparations without usurping the rights of the physician or becoming unethical? Would there be any difference, ethically, in marketing preparations made by the druggist or those made by some co-operative organization to which he belongs? Would there be any difference from the same standpoint between preparations of such

a co-operative organization and any regular patent medicine manufacturer?

9. What do you think of tinctures made by diluting fluid extracts? Should formulas for making tinctures that way, be given on fluid extract bottles?
10. What are essential qualities of a good cold cream? A good hand lotion? Can you offer a formula embodying these qualities?
11. What arguments have you in favor of the retail druggist making his own tinctures, syrups, elixirs and other simple pharmaceuticals? Have you any arguments against such practice?
12. How much of the trouble encountered by pharmacists in making official preparations is due to the use of crude materials of improper quality and subsequent improper keeping of the finished product?
13. Did you find it necessary to have your pharmacopœia rebound before it has been subjected to much wear? Is the binding as substantial as it should be or does it compare favorably with the binding of other books intended for constant use?
14. Has the average pharmacist such reference books as he should have? Would \$50.00 to \$100.00 expended on books of value to pharmacists be a paying investment from a commercial standpoint? What books would you include in five feet of reference books for the country pharmacist? The city pharmacist?
15. Do pharmacists as a rule select the right kind of boys for apprentices, considering they are the timber from which pharmacy of tomorrow will be built?
16. What plan would you suggest to make our profession more attractive to the better class of young men?

THE GERMAN APOTHECARIES' TOUR.

The sympathy of the JOURNAL and of the members will go out to those participating in the European Tour of this society, on its summary interruption. On Friday, July 24, the party was scheduled for Vienna, the focus of the disturbance, and the day before the declaration of war they were to have been at Strasburg. In view of the disturbed state of the districts included in their itinerary, it is too much to hope that they will not experience great annoyance and that the trip can be further pursued. Our members accompanying the party are:— Gustav Bachmann, Mr. and Mrs. F. A. Bongartz, Mr. and Mrs. O. F. Clauss, Mr. and Mrs. F. W. Connolly, H. A. B. Dunning, Mr. and Mrs. T. Griffin, H. Kantrowitz and daughter, Mr. and Mrs. G. Kring, R. S. Lehman, Dr. A. W. Miller, Mrs. Charles Rehffuss, Leonette Rehffuss, E. W. Runyon and wife, H. W. Schimpf, Mr. and Mrs. T. H. Tucker, Mr. and Mrs. P. H. Utech.

A CORRECTION.

BROOKLYN, N. Y., July 18, 1914.

The Editor of the Journal:

DEAR SIR—Referring to your editorial about the Convention City, allow me to say that the French word "*etroit*" means "narrow," and D'*etroit* by derivation means the place on the narrow (of the river). Compare: Des Moines, the place of the monks. You see how near and natural the derivation really is.

I appreciate the JOURNAL so highly that I do not like to let this little *faux pas* pass unnoticed. Sincerely yours,

LORENTZ CANTOR.

<>

For the Editor:

I write about a matter dear to my heart. I desire to awaken an interest in a National Veteran Druggists' Association under the auspices of the A. Ph. A. If the requirements for membership of the Chicago Veteran's Association were adopted by such an Association, viz., twenty-five years' connection with pharmacy and the furnishing of a photograph and autobiography, the future historian of American Pharmacy would have "a cinch." Give me the autobiography of the present leaders,—and—you have the History of Pharmacy. And if the Chicago experience is repeated in the country at large, most men will have less trouble to write their biography before their funeral than after.

Men who make their mark, generally come to the surface in the space of time of a quarter-century.

I would suggest that local chapters be formed in larger cities, or in counties or states, but let the A. Ph. A. be the focus.

Whether the local chapters will write Goodfellowship on their banner is a matter for them to settle. But, if you ask for my opinion, I say in hundred horse-power voice, "Let Goodfellowship Reign Supreme."

We, in Chicago, prohibit the discussion of business, religion or politics at our meetings; thus avoiding all infection of friction microphone. We lead, uplift, and reform professional spell-binders and speakers, and don't touch the blessed article "Reform." Aside from these, nothing is prohibited, not even indulgence in cold water;—but no cold hearts are tolerated.

The principle of our branch is to foster

the *entente cordiale*, to cast a hue of gold over the setting sun, and to demonstrate the fact that filthy lucre is not paramount everywhere. With us, all are alike, rich or poor,—all are friends,—all work for all and one for all,—and our emblem, a pink carnation, blazes the way,—in burning rays,—

"Cheers for the living, and tears for the dead."

I wish the leading members to give the matter a pre-convention thought. I am satisfied to start the Krupp Guard of the A. Ph. A., the organizers, to thought on this subject.

If these constructing and consulting engineers formulate a working formula, I feel fully recompensed in having started "the ball rolling."

W. BODEMANN.

<>

THE DRUGGISTS' NATIONAL HOME.

To the Editor:

Probably every druggist in the United States knows the history of the Home. A property costing some \$120,000, was sold to the druggists of the United States for \$60,000, this including repairs.

Some \$10,000 was sent in and the prospect looked good to have it all paid for in a few months. During the summer of 1913 the Home was open to all and was well patronized. We were promised donations from all over the United States. The property was bought on the lease system, the trustees signing papers that if \$20,000 was not paid by April 10, 1914, the property would revert back to the owner with all repairs. During the winter of 1913-1914 the house was practically closed, only three people being there. The trustees became discouraged, and one by one they resigned their offices, until only I was left.

April 10 Mr. Hedenburg claimed the property according to the contract, and it was turned back to him. He then stated he had done this to protect himself, and he then appointed me his agent and put me in charge of the property, and with the understanding the deal was still open to the druggists of the country, and he (Mr. Hedenburg), would give them the first chance.

Mr. Hedenburg and I am still sanguine over it that the druggists will rally and accept this beautiful place. Since October I have cared for the place without any charges. May 1, 1914, the Home was opened for the reception of visiting druggists and

has been visited by many to prove the statements made by the trustees that it has paid expenses so far this season. It is now open to all who wish to make it a visit.

The property, as stated, cost \$120,000—it was bought for \$60,000. It is now in good repair and we can have it according to the original contract. We have fifteen applications, now, for admission. All of them are from old druggists who have spent a lifetime in their work, and are now "down and out."

We have six other applications from old druggists who have money and can and will pay a good price, but want to spend their

days at the Home. If the N. A. R. D. and the American Pharmaceutical Association would take this up, appoint the trustees from their executive committees, the entire sum could be raised in a short time and in five years the place would be self-sustaining. At present there are no officers, so it will be only necessary to elect a board of managers. The full amount need not be paid down. Two dollars and a half per year (5 cigars) from each druggist in the U. S. will give us and sustain for us a Home that we will all be proud of.

Respectfully,

E. B. HEIMSTREET.

Book Reviews

THE BULLETIN OF THE MASSACHUSETTS COLLEGE OF PHARMACY, June, 1914. Published by the College. Edited by Theodore J. Bradley, Dean.

The very excellent *brochure* of the College has come to the A. E.'s table full of interesting matter in relation to the M. C. P. Its special items are the report of Treasurer Godding, which shows the College to have assets over all liabilities of \$238,227.94; the comment upon the Course in Commercial Pharmacy, conducted by Professor La Pierre; President Packard's address in full to the graduating class of this year, and the address of Joseph H. Cooney, a member of the class of this year on "Cut Prices."

The entire *ensemble* of the Bulletin is most praiseworthy from cover to cover.

THE PHARMACEUTICAL SYLLABUS. Second Edition. Outlining a Minimum Course of Instruction of Twelve Hundred Hours. Revised and Published by the National Committee, Representing The American Pharmaceutical Association, American Committee of Pharmaceutical Faculties, National Association of the Boards of Pharmacy. Copyrighted. All rights reserved. Price \$1.25. Postage 10 cents.

The pharmaceutical profession will welcome this syllabus with enthusiasm, for it is the first one published in this country of a national character, and one which will have a most potent and beneficial effect upon pharmaceutical education throughout the country, and which, by the elevation of instruction, will give to pharmacy a standing, long-jeopardized by lax and inefficient standards, varying according to locality and individual opinion.

Here is a well-ordered plan of instruction, which, if definitely adhered to, will result in immense advantage to the profession.

The committee are to be congratulated on their admirable work and they should receive the thanks of every well-wisher for pharmacy in the world, and it is earnestly to be hoped that no time will be lost in the adoption of this plan of instruction by every institution in the United States.

Copies may be secured of H. I. Taylor, Treasurer, Albany, New York.

Section on Commercial Interests

Papers Presented at the Sixty-First Annual Convention

SHAPE OF TABLETS FOR EXTERNAL USE.

OTTO RAUBENHEIMER, PHAR. D., BROOKLYN, N. Y.

The manufacture of tablets and, quite especially, their evolution, is unquestionably an American innovation. From the compression of a pill, the *flat, round* shape of the tablet has resulted, and it has become the custom to manufacture tablets of this particular shape throughout the civilized world. In the course of time, larger tablets have been manufactured, such as lithia tablets, which were very convenient for the extemporaneous preparation of lithia water. Next came tablets, which were intended for the preparation of solutions for external use, some of which were even of a poisonous nature. It has undoubtedly been a very serious mistake to manufacture tablets for external use, of identically the same shape of those for internal use, as they can easily be mistaken for one another, even by physicians themselves. On account of the many, the very many, accidents, some of which have even proven fatal, from the internal use of "Bichloride Tablets," which have usually been mistaken for headache tablets, numerous suggestions as to color and shape have been made. The craniums of pharmacists, chemists and even those of the public have been quite busy in making suggestions.

Color: There is no question but that the color of the poisonous tablet exerts some psychological action upon the patient or the public. The German Pharmacopœia in the case of "Bichloride Tablets" orders a red color by means of eosine. The supplement of 1891 of the Netherlands Pharmacopœia, 3rd edition, specifies a blue color, which is also used in Russia. In the United States "Bichloride Tablets" have been manufactured of a white, blue, green and red color.

Shape of Bichloride Tablets: Ever since "Bichloride Tablets" have become official in the 3rd edition of the German Pharmacopœia (1890) they have been made of cylindrical shape, about twice as long as thick. At least three manufacturers in the United States have realized the necessity of a special shape of these poisonous tablets, one making them diamond shape, another clover-leaf shape, and the third in the shape of a triangle. There is no question that these distinctive shapes have contributed to prevent accidental poisonings. As a further precaution "Bichloride Tablets" in the United States are also put up in distinctively-shaped bottles, of rough corrugated exterior, these bearing a poison-label, and in addition, each tablet is stamped "Poison."

A great many suggestions have been made regarding the proper shape of the

deadly "Bichloride Tablet." A former chairman of the Section of Pharmacy and Dispensing of the A. Ph. A. is of the opinion that the shape of a coffin, adorned with skull and cross-bones, should be adopted as the proper shape and that this will prove an efficient safeguard. Another active A. Ph. A. member suggests the grotesque shape of a skull, or the peculiar form of a kidney. There is no question but that all these suggestions have been made in good faith, with the sole object of safe-guarding the patient and the community.

Shape of Tablets for External Use: The Bichloride "accidents" have plainly demonstrated the desirability and also the necessity of a *distinctive and uniform shape of tablets for external use*. The tablets for internal administration are round, and this shape, which has been adopted throughout the civilized world, cannot be very well changed. What is needed, and needed very badly, is a distinctive shape, *but not a fancy shape*, of tablets for external use. The writer has given this subject much consideration. He has reached the very simple conclusion that all tablets for external use should be made *Flat* and *Square*, with four corners and that these corners should not be rounded.

Advantages of Square Tablets for External Use: 1. A distinctive square shaped tablet cannot be *mistaken* for a round tablet at any time.

2. The tablet has four corners and thus it will mark plainly its use for solutions intended for external application.

3. Such a tablet cannot be easily swallowed as, owing to its four corners, it is liable to stick in the throat.

4. By being *Flat* and *not Cubical* the tablet can readily be broken into several pieces, to increase its solubility.

Poisonous External Use Tablets: If the external-use tablet is poisonous, then, in the opinion of the author, the following precautions should be taken:—

1. The tablet should be square and flat.

2. The tablet should be colored.

3. Each tablet should be wrapped *individually*, and the wrapper should be marked "Poison."

As to the proper color for a poison tablet, I would recommend eosine. Red has always been the danger-signal and for that reason, the psychological action of a red tablet might be stronger to prevent mistake than that of any other color. As to the individual wrapping, the author is in favor of the German method in the case of "Bichloride Tablets," namely the wrapping of each tablet with black paper, which in white letters bears the name "Poison," as well as the skull and cross-bones.

Conclusion. In view of the enormous use of tablets in the United States, I would make the following three additional recommendations:—

1. The adoption of a monograph or general chapter on tablets, in one of our legal standards, the U. S. P. or the N. F. It might be news to some pharmacists in the United States, to learn that a Chapter on Tablet Triturates is official in the National Formulary under "Pulveres" as "Pulveres in Tablettis."

2. That the U. S. P. or N. F. should make an explicit statement that *all tablets for external use* should be made of a *square and flat shape*.

3. That *poisonous tablets* intended for external use should have the same

square shape, should be *colored*, and should be wrapped *individually with black paper* which in *white ink* bears the word "*Poison*."

By the adoption of these simple recommendations, the dispensing and the use of external tablets and poison tablets would be thoroughly safe-guarded. The adoption of these simple recommendations would result in uniformity in the shape of these tablets all over the United States and this arrangement would be far more desirable than the enactment of heterogeneous laws by different states, which would result in a multiplicity of shapes and colors for such tablets, and be a hardship for manufacturers and pharmacists. Remember, *round* tablets for *internal* administration and *square* tablets for *external* use only. Let us be "on the square!"

DISCUSSION.

Mr. Mayo said there was one objection he could see to the use of eosin, and that was, that a color for poison should be selected which was characteristic. A pink, or any shade of red, was not sufficiently characteristic, as there were already so many tablets colored in that way that it would be no indication of any peculiarity. There were no tablets, so far as he was aware, that were colored blue, except methylene-blue tablets, and blue was a color which had been adopted for corrosive sublimate in hospitals. The suggestion offered by the author did not include the specific name of a color. He wished to move, therefore, that the Section on Practical Pharmacy and Dispensing recommend to the House of Delegates the passage of a resolution suggesting the introduction into the Pharmacopoeia of a monograph on tablets in accordance with the suggestions contained in Mr. Raubenheimer's paper. He expressed his satisfaction that the author had not specified any color, because he did not think any shade of pink was desirable, either in U. S. P. or N. F.

Mr. Nitardy moved to amend, that Mr. Raubenheimer and Mr. Mayo be appointed as a committee to draw up suitable resolutions to be introduced in the House of Delegates.

This motion was seconded by Doctor Schneider; but the Chair suggested that this matter be presented a little later, when there were more members present, and so the matter was passed.

Mr. Raubenheimer made the suggestion in regard to blue, that it was very difficult to get a blue color which was permanent, because all blues, except one, as he recalled, were reduced by bichloride. There was only one blue color that could be used.

Mr. Mayo replied that "One was a-plenty."

Mr. Windloph said he did not know whether Mr. Mayo was referring to tablets for internal use, and suggested that his establishment manufactured bichloride tablets colored blue.

Mr. Mittlebach thought that conscientious druggists throughout the country were anxiously awaiting a solution of this problem of throwing around the use of these dangerous tablets some adequate safeguard. Mr. Raubenheimer, he said, had been working faithfully to this end; he had read some of his papers on this subject. It occurred to him that some other word than "tablet" might be coined to meet this situation. A tablet meant something taken internally, and he thought it would be a decided advantage if some other word could be used to express the idea in mind. He also thought it would be well to put these dangerous tablets on the market in small packages, with permission to dispensers to sell them in original package only. The trouble was the result, usually of the breaking of the package, as was the habit with many druggists throughout the country. They often sell these strong poisonous tablets in pill-boxes, or in some other way, not distinctive, and they were taken home by the purchaser and put in the medicine-closet, alongside of aspirin tablets, in a box of perhaps the same shape, with the result that mistakes often occurred. If druggists could be compelled to sell these poisonous tablets in original packages only, in some proper and distinctive shape, he was satisfied it would "help the cause."

Chairman Lascoff commended this as a good suggestion.

Papers Presented at the Sixty-First Annual Convention

SOME OBJECTIONS TO MATERIA MEDICA STANDARDIZATION WITH REFERENCE TO THE U. S. PHARMACOPŒIA.*

F. E. STEWART, PH. G., M. D.

The text of my sermon will be found in the Journal of the American Medical Association for Nov. 30, 1909, p. 1645: "A thoroughly up-to-date Pharmacopœia—one which will truly reflect the best medical practice of the present time—will contribute more to sane drug therapeutics than any other one thing."

To prepare a new materia medica product for introduction into the United States Pharmacopœia, it is necessary first, to give it a name conformable with scientific nomenclature, (the first step in standardization). This is objected to by certain commercial interests who desire property-rights in the name of each new product, for the purpose of creating a lasting monopoly in its manufacture and sale.

The next step consists in the free discussion of each new drug in medical and pharmaceutical journals, societies, schools and colleges. Certain objectors are entirely in accord with such discussion, provided the discussion is favorable to the therapeutic claims they make for their controlled products. But free and impartial discussion, when it results in diminishing sales, is not viewed with equanimity by commercial introducers, after they have spent, possibly, a hundred thousand dollars in advertising.

The next step is the fixing of tests for identity and purity, and the enforcing of the standards thus evolved by pure food and drug laws. Honest manufacturing houses favor this kind of legislation. It is only the dishonest manufacturers who object.

The standardization of galenical products, to fit them for a place in the Pharmacopœia, includes determination of botanic source, physical and chemical structure, pharmaco-dynamic and therapy-dynamic properties, and therapeutic uses. Manufacturers depending upon concealing one or more of these factors, to obtain and retain monopoly of sales, object to such standardization.

Again, manufacturers depending upon a fictitious demand, created by misleading advertising, object to standardization.

Another objection to standardization, is, that standardization means *leveling* of all materia medica products to common standards, thus taking away from commercial introducers, the advantage to be derived from advertising their products as better than those of their competitors.

*Read before the Section of Pharmacopœias and Formularies at the Nashville Meeting, August, 1913.

What the medical profession must know in order to treat the sick properly, are the side-effects, limitations and comparative value of new products, in their relation to each other, and to older and better known products, employed as therapeutic agents in similar conditions. It is just this kind of levelization, that the medical and pharmaceutical professions must insist upon, if we are ever to restore public confidence in drugs as remedial agents.

Suppose that the manufacturers of potassium iodide, were able to do so, and should, organize a campaign against the newer syphilitic remedies, because their success meant injury to the sale of potassium iodide. Suppose the manufacturers of quinine should endeavor to prevent the destruction of mosquitoes because malaria is propagated by mosquitoes and the sale of quinine is dependent upon the existence of malaria. Such action on the part of the manufacturers, would be bitterly resented by the public. Yet this kind of opposition to the therapeutic standardization of new materia medica products, is actually going on at the present time.

Demand created by false advertising of unwarranted claims, represents unfair competition. Business taken away from competitors, in this way, is stolen. The remedy for unfair competition, is to be found in drug-standardization. It is not surprising that those guilty of unfair competition object.

Let me quote the exaggerated claims made for a certain alleged new remedy by way of illustration. I have coined the name "Antigonensis" to describe the advertised product.

"Antigonensis is a powerful and harmless systemic antiseptic in the most varied medical and surgical infections. It checks beginning sepses and often effects brilliant recoveries in desperate ones. Recent investigations show that, with its direct bactericide energy, it exerts a marked electrolytic and leucocytogenetic action, and thus greatly aids the natural protective forces of the body.

"Used topically, by mouth, rectally, intravenously or by inunction, Antigonensis forestalls the development of sepsis from accidental or operative wounds, or childbirth, arrests beginning medical and surgical infections, and often achieves brilliant recoveries in apparently hopeless cases."

It is evident that pharmaceutic and therapeutic standardization, would soon "levelize" this product and rob the manufacturer of the advantage to be obtained by claiming it to be better than competing products.

The true ideal of pharmacologic practice includes coöperation between the medical and pharmaceutical professions, and the manufacturing houses supplying them with materia medica products, to prevent such kind of advertising. This coöperation can never be secured, until all concerned are willing to consider the public health, as of greater importance; than the *making of money*. It is admitted that the *making of money*, is absolutely necessary, for the existence of the doctor, druggist and manufacturer. The doctor must live on his fees, the pharmacist on his sales of medicines, and the manufacturer on the profit obtained by selling his wares. But dishonest commercialism should be abolished. The principle expressed by the motto "caveat emptor" (let the purchaser beware) is a very dangerous principle, applied to medicine or pharmacy.

Objections to materia medica standardization, come from manufacturers of commercially-controlled materia medica products of all kinds. For the purpose

of obtaining a clear conception of the objections and objectors, let us classify the objectors into their classes as follows:

1. Secret Medicine Manufacturers.

a. Retail druggists supplying medicine of their own make, which they recommend for self-medication, trusting patients to make their own diagnosis for the most part, but sometimes venturing to make a diagnosis for them.

b. So-called "patent" or proprietary medicine manufacturers, who prescribe medicine at wholesale, without diagnosis.

2. Manufacturing Chemists and Pharmacists dealing in commercially-controlled specialties.

a. Manufacturers of medicinal-mixtures of secret formulas, for doctors to prescribe.

b. Manufacturers of mixtures concerning which the medicinal ingredients are published, but regarding which the working formulas are suppressed.

c. Manufacturers of chemical synthetics protected by patent, and registered names.

The objectors to standardization, are as varied as the character of the manufacturers. Behind the objections, are motives equally complex. All object, because they do not want to part with their monopolies. Some object, because, in addition to that reason they wish to create a demand by misleading advertising.

"How can inventors protect capital, invested in the working and development of new inventions, from interference and competition, if inventors publish full knowledge of their inventions, for the benefit of scientific classification and standardization?" This question is frequently asked by the pharmacists and the reputable manufacturers, engaged in the pharmacal and pharmaco-chemical industries.

The answer is to be found in that clause of the Constitution of the United States, that gives to Congress the power "to promote the progress of science and the useful arts, by securing, for limited times, to authors and inventors, the exclusive right to their respective writings and discoveries."

Inventors of new and useful arts, machines, manufactures, and composition of matter, may obtain proper protection by patenting their inventions.

There are good reasons for believing, that the proper application of the patent-law to medical inventions, would promote progress in medical science and in the useful arts of pharmacy and drug-therapy. But to accomplish this object, it would be necessary to establish some kind of a commission, board of control, or bureau of materia medica, working with the Patent Office and the Courts, to limit the patenting of materia medica products to substances new and useful, *in fact*, also to act as experts in infringement-cases, requiring higher knowledge of medical and chemical science and arts, than that possessed by the legal fraternity.

The patenting of new materia medica inventions under such a board of control, would promote materia medica standardization. For the statute exacts, "That, before any inventor or discoverer shall receive a patent for his invention or discovery, he shall make application therefor, in writing, to the Commissioner, and shall file, in the Patent Office, a written description of the same, and of the manner and process of making, constructing, compounding, and using it, in such full, clear, concise and exact terms, as to enable any person skilled in the art or

science to which it appertains, to make, construct, compound and use the same."

It may be answered that the prejudice against patenting materia medica inventions manifested by the medical profession is a serious hindrance. This is true. However, this prejudice might, in all probability, be overcome by the adoption of some plan to prevent dishonest exploitation of new materia medica products by commercial introducers, also to secure free and impartial discussion of commercially-controlled products by the medical and pharmaceutical press.

Much has been done in this direction by the Council on Pharmacy and Chemistry of the American Medical Association, and much by the pure food and drug laws. The Shirley amendment to the national pure food and drug act, aimed against misleading advertising, if properly enforced, will be of great service. Similar bills advocated by "Printers Ink" are being passed by the States, and, as they are backed by the advertising fraternity and their agents, we have a right to expect salutary reform. But we need some kind of strong central board of control, in which the various interests involved may be represented, and have a voice in the administration of affairs.

"But," say some of the objectors, "the seventeen year limit, provided by the patent law, is not long enough to get our money back. It requires an investment of at least one hundred thousand dollars in advertising a new product, before the investment becomes remunerative. And it must also be considered that a certain proportion of ventures prove unprofitable. That is why we devised the scheme of patenting our products, under their chemical names, and registering coined names as trade-marks, to be advertised as the names of the products. By forcing the coined names into the common language, as nouns, and retaining ownership in them, we are enabled to extend our monopolies indefinitely."

This plan, for defeating the object of the patent-laws, was set aside by the decision of the Supreme Court of the United States, in the Singer Sewing Machine case in 1895. According to this decision, the name of a patented article cannot be commercially-controlled after the patent expires.

"Then why 'patent' materia medica products at all?" say the objectors. "Why not 'trade-mark' them, and keep the process of their manufacture secret? A trade-mark never expires and the manufacturer, by controlling the name of the product, possesses a perpetual patent."

The weakness of this argument is apparent, when one considers that any person who discovers, by legitimate means, how to make the same product, has the right to do so, and advertise the fact. He also has the right to employ its currently-used name, either as the title of the product or as a synonym. For example, what is to hinder any manufacturer of hexamethylamine from using on his label, as synonyms, all of the fourteen so-called trade names or trade marks of that drug?

"We are perfectly willing to aid the government in fixing standards for our products and placing them in the Pharmacopœia, if we can still maintain monopoly," say the objectors. "What we desire is, to secure the advertising advantage of having our products listed in pharmacopœias, dispensatories, medical dictionaries, text books and other medical and pharmaceutical literature. We also desire discussion in professional journals and societies. We want the medical

colleges to teach the students how to use our products. But we want to hold on to them."

That is the same as saying, that these objectors want the medical and pharmaceutical professions, colleges, societies and press, to do their detail-work without pay. "No," say the objectors, "we are willing to pay for the work, if we can get it done in this way. What we object to, is giving up our monopoly."

To this, medical scientists reply that to do the work for pay, would be the same as going into partnership with the manufacturers in a commercial business, and the turning of the educational machinery of the profession into a great advertising bureau for the commercial exploiting of alleged "new remedies." Those engaged in materia medica commerce, are no longer in a judicial position in relation to materia medica, and what they say about it must be received *cum grano salis*.

If this objection is true, then the professional ideals taught by the colleges of pharmacy are false, and there can be no profession of pharmacy.

But is it true? I do not believe it. It becomes evident that pharmacy is a profession, when it is considered that the proper introduction of new materia medica products requires the coöperative work of physicians, pharmacists, chemists, botanists, bacteriologists and other professional men, learned in the knowledge of their respective branches and expert in *technic*. Coöperation on the part of the professional societies and press, is also required. The result of this coöperative work belongs to the workers, not to individuals. It must be contributed to the common fund, for the benefit of all concerned. This means, that the introduction of new materia medica products, should be changed from a commercial or monopolistic plan, to a professional or coöperative plan.

Now we are in position to consider the question of patenting new materia medica products, in connection with a professional system. It seems to me, that the question is one for the professions of pharmacy and medicine to decide. If they are willing to consent to it, as adapted to the promotion of progress in medical science, and in the arts of pharmacy and drug therapy, then let it be done.

But it is evident that it is unfair to ask any one person or manufacturing house, to do business on a professional basis, while competitors are doing the same business on a commercial basis.

Until manufacturers are willing to place their business upon a professional basis, they have no right to expect professional coöperation. I believe that the profession is willing to endorse and coöperate with manufacturers, under the protections of the patent laws, just as they are willing to coöperate with the publishing houses, under the protection of the copyright laws, provided that medical science and the arts can be promoted thereby.

The object of the copyright and patent laws, is to promote progress in science and the useful arts, by securing, to authors and inventors, the right to prevent others from copying their respective writings and discoveries for limited times. The object of the trade-mark law is to protect all concerned, from the counterfeiting of labels and brand-marks. But all plans for obtaining and fostering perpetual monopolies, are a hindrance to science, and stand in the way of prog-

ress in civilization. Monopolies of this character, ought to be opposed by all patriotic citizens, and especially by physicians and pharmacists.

It is evident from the foregoing that a thoroughly up-to-date pharmacopœia will contribute more to sane drug therapeutics than any other one thing. The U. S. Pharmacopœia is preëminently the standard for medicinal drugs, chemicals and pharmaceutical preparations in the United States. It is the basis upon which rests all materia medica literature, including the dispensatories and text books. The information contained in the Pharmacopœia, is taught in the medical and pharmaceutical schools and colleges, and circulated throughout the country, in the literature of pharmacy, chemistry, and therapeutics.

The U. S. Pharmacopœia is "the law of the land," not only for Inter-state commerce, but also for state commerce, in most of the States. Whatever goes into it, is placed there, after mature consideration by a convention of representative physicians, pharmacists and chemists, who, collectively, decide its policy and appoint the committee for its decennial revision. The influence of the Pharmacopœia upon the pharmaceutic, pharmaco-chemic, and therapeutic arts is therefore incalculable.

To prepare new materia medica products for admission to the Pharmacopœia, their standardization is necessary. Materia Medica products cannot be properly standardized, except by the coöperative work of the medical, pharmacal, and chemical professions, whose functions are to determine, for each product, its nomenclature, source or genesis, physical and chemical properties, pharmacodynamic and therapy-dynamic actions, therapeutic applications, and proper methods of preparation. This function is being constantly exercised by the Committee having charge of the revision of the Pharmacopœia.

To obtain a thoroughly up-to-date Pharmacopœia, the commercially-controlled materia medica must be considered. The rule adopted concerning the admission of controlled-materia medica products, to the Pharmacopœia follows,—the Committee was authorized to admit,

"Any synthetized product of definite composition which is in common use by the medical profession, the identity, purity, or strength of which can be determined. No compound or mixture shall be introduced, if the compositions or mode of manufacture thereof be kept secret, or if it be controlled by unlimited proprietary patent rights."

Some of the synthetic products still controlled by patents were admitted, because the patents were about to expire. So-called "trade names" were not admitted. Abbreviations for long chemical names were coined and adopted.

In the light of the above facts, it is evident that the rule adopted by the committee, which was doubtless the best that could be devised under circumstances then existing, is not adequate to secure proper standardization. Something should be done to clear up the question of nomenclature, so that a new product may be admitted under its currently-used name, the same to be adopted either as the official title or as a synonym. Also the question of ethics, in regard to patenting new materia medica products, either as to product, or process, or both, should be decided, and proper action taken in the premises.

The proper application of the patent law to materia medica inventions, the same to be administered under the advertisement of a board of control, repre-

sentative in character, working with the Patent Office and the Courts, would probably result in securing the object of the patent law in this connection, i. e., the promotion of progress in medical science, and in the useful arts of pharmacy, chemistry and drug therapeutics.

The *personnel* of such a board of control is well exemplified by the U. S. P. Revision Committee. It is truly representative in character, and is already engaged in the work of standardization. If to this Committee, Congress would give advisory authority to act in expert capacity, in conjunction with the Patent Office and the Courts, and would provide sufficient appropriation to meet the necessary expense, all objections to drug standardization, on the part of inventors and manufacturers, would disappear, also the ethical problem would be solved, and an embarrassing situation relieved.

THE PHARMACOPŒIA, THE DRUGGIST AND THE PHYSICIAN.*

R. H. NEEDHAM.

That the Pharmacopœia is the "Book of Books" among chemical and pharmaceutical publications must be conceded, when we look about and, after reviewing the great mass of literature, we find that we are compelled to turn to it, as a rule and guide in selecting and standardizing drugs and chemicals. It is not perfect, and probably never will be, but this does not detract nor lessen its value, when considering it as a book of standards, because there is no other work equal to it, let alone being its superior.

Druggists who are familiar with the Pharmacopœia are aware of its value, though we regret to say that but few of them make any use of it, except as a reference to simples. When it comes to formulas and preparations, almost every one of the rank and file, consult a Dispensary, instead of the Pharmacopœia. As a Dispensary consists of notes taken from one or more pharmacopœias, the matter is second-hand in a way, and coming from so many sources, it gives the reader, if he is not very careful, quite confused ideas as to some preparations. Druggists will not agree upon the procedure for making a preparation for this reason, each claiming their preparations U. S. P. Should you ask them to make the preparation, using the U. S. P. text, you would be apt to receive a mild protest, as they would probably inform you that they preferred to use the Dispensary rather than the Pharmacopœia as the latter gives all quantities in the metric system and they have difficulty in converting weights and measures. I consider it a shame and disgrace for the druggist to make such an excuse, when metric weights and measures can be so readily obtained and at such reasonable prices. Yet this bugbear is in the way, and nothing short of a national law making the metric system the official one will place the pharmacopœia where it ought to be among the druggists.

From my view-point and experience in teaching, I wish the other systems of

*Read before the Section of Pharmacopœias and Formularies at the Nashville Meeting of the A. Ph. A., August, 1913.

weights and measures were buried and forgotten and I further wish that the new Dispensatory would omit old forms entirely.

I fail to see how we are to make any headway with physicians concerning the Pharmacopœia under present conditions. First, until the metric system is forced upon the doctors they will neither read or write it, but will continue to use the old forms. In the second place, I declare, without fear of contradiction, that they are being educated away from the pharmacopœia instead of toward it. I refer to scholastic courses of education, now, and not to commercial education.

We all know where the latter leads to, without further comment. When the time for teaching *Materia Medica* and Pharmacy are so shortened as to give but thirty to forty hours' work in medical courses, kindly tell me, how, when, or where, can an instructor find time enough to teach anything concerning the pharmacopœia or of its listed drugs and preparations. I have tried for several years, asking for more time each year, in return being assigned shorter hours, until I am asked this year to teach these two important subjects within twenty-five hours. The *curricula* of other medical schools are following the same plan and a remonstrance is met with the declaration that the student does not need a longer time. Pharmacology and therapeutics are the important subjects, consequently our future physicians will know nothing of the pharmacopœia, except as an authority to be quoted, never to be used. Neither is there any time or place for the National Formulary. Thus we perceive that while the druggist may acquire a very complete knowledge of the pharmacopœia the practical application largely ceases when we reach the physician, because of his ignorance regarding it.

We must be alive to these conditions and exert a different influence in educational matters, else we as druggists will some day awake to the fact that the pharmacopœia will be the center of attraction of a mutual admiration society, composed of all other scientists, to the exclusion of the practicing physician.

THE NEED FOR GREATER UNIFORMITY IN LAWS RELATING TO THE MANUFACTURE, SALE AND USE OF POISONS AND HABIT-FORMING DRUGS.*

M. I. WILBERT, PH. M., WASHINGTON, D. C.

The untoward harm that might result from the promiscuous distribution of admittedly potent drugs and chemical substances was early recognized as being sufficient reason for the enactment of legislation designed to restrict the manufacture, sale and use of articles that might reasonably be classed as poisons or habit-forming.

Based on this generally accepted need, laws have been enacted for practically every political division constituting what is now designated as the United States. A compilation of the essential features of these several laws has been made, in

*Read before the Section on Education and Legislation at the Nashville Meeting of the A. Ph. A., August, 1913.

connection with a general study of the laws relating to public health matters, by the Public Health Service of the United States, and published as Public Health Bulletin No. 56, entitled a "Digest of Laws and Regulations in force in the United States Relating to the Possession, Use, Sale and Manufacture of Poisons and Habit-Forming Drugs." Even the most cursory comparative review of the requirements embodied in the several laws included in this compilation will suggest the imperative need for some form of correlation between these laws and the desirability of having greater uniformity in their general provisions and requirements. To bring this matter more directly to the attention of pharmacists, who, above all, should be interested in the efficiency and equity of laws of this kind, I have endeavored to compile some of the requirements in statistical form.

In connection with the laws regulating the practice of pharmacy, it may be pointed out that all of the fifty-four political divisions enumerated have some form of pharmacy law. Two states, New York and Pennsylvania, require graduation, and a third state, North Dakota, will require graduation in 1915 as a prerequisite to registration. Forty-four of the political divisions by statute-law require practical experience, four require five years' training, thirty require four years and ten require three years. In three of the remaining states, the boards of pharmacy have adopted regulations requiring four years of practical experience, or its equivalent, for registration. Forty-two of the political divisions provide for revocation of license for cause. In forty-one political divisions the pharmacy laws apply only to retail drug stores. In but two states, California and Oregon, are the manufacture of drugs mentioned, and in two other political divisions, the State of Washington and the District of Columbia, the law applies, equally, to wholesale and retail dealers. In seven additional political divisions, the law can be interpreted to apply to other than retail dealers.

In connection with the provisions relating to the manufacture, sale and use of poisons, the variation is equally great, if not greater. Up to the present time, no satisfactory definition for the word "poison" appears to be available, and the several laws vary, from "any substance which, in doses of 5 grains or less, is destructive to human life" to "any drug, chemical, medicine or preparation liable to be destructive to adult human life in quantities of 60 grains or less." In some states the law is made to apply to "any deadly drugs"; "any article belonging to the class of medicines usually denominated poisons," or "articles of a nature poisonous to the human system or to animals."

Equally chaotic conditions exist in connection with the schedules of poisons included in the several laws, as now enforced; these laws enumerate a total of one hundred and sixty-four articles. Thirty-nine of these occur but once, twenty-seven occur twice and twenty occur three times. The following table presents a list of the articles enumerated most frequently, in the order of their occurrence:

Corrosive Sublimate	in 38 laws
Opium	" 36 "
Chloroform	" 35 "
Carbolic Acid	" 34 "
Arsenic	" 34 "
Oxalic Acid	" 33 "
Hydrocyanic Acid	" 32 "
Potassium Cyanide	" 30 "

Arsenic, preparations of.....	in 29 laws
Croton Oil	" 27 "
Chloral Hydrate	" 26 "
Mineral Acids	" 25 "
Aconite and preparations.....	" 25 "
Belladonna "	" 25 "
Digitalis "	" 25 "
Cotton root "	" 24 "
Strychnine	" 24 "
Oil of Savin.....	" 23 "
Ergot and its preparations.....	" 22 "
Oil of Tansy.....	" 22 "
Cantharides and its preparations.....	" 21 "
Nux vomica "	" 21 "
Oil of Almonds, essential.....	" 20 "
Creosote	" 20 "

Among other frequently mentioned drugs and preparations, are conium (18), colchicum (17), Henbane (14) and veratrum viride (13). Strangely enough, morphine in its several forms, occurs in but a total of 16 laws. Cocaine and its salts are enumerated in 14 laws, and "coca or its preparations or alkaloids" occurs in but one. Among other substances that occur but once, are salts of barium, arsenate of copper, sulphate of copper, compound solution of cresol, ether, nitroglycerin and santonin. This feature of the laws relating to the sale of poisons, is no more variable than are the other restrictions usually included in these laws. For instance, of the fifty-four laws now in force, fifty require the word "poison" on the bottle or container, though there are a number of variations in the requirements as to how the word is to occur. Thirteen laws require the enumeration of antidotes on the label. Forty-five laws require some form of poison-register and thirty require that the seller make due inquiry that the substance is to be used for a lawful purpose.

Legislation designed to restrict the sale of narcotic drugs, is equally variable, and, in this connection, it may be pointed out that while thirty political divisions restrict the sale of opium, only seven laws include "the alkaloids of opium." Twenty-seven mention morphine, five mention codeine, sixteen mention heroin and sixteen include derivatives of the substances enumerated. The sale of cocaine is legislated against in no less than forty-eight of the political divisions, but so far as known, only sixteen restrict the sale of hydrated chloral.

In thirty-one of the political divisions, the law requires the preservation of prescriptions or orders for narcotic drugs. Eight of these laws do not specify the period of time, one requires preservation for one year, three require preservation for two years, one requires preservation for three years, seven require preservation for five years, and no less than eleven require that the prescription be permanently kept on file.

Up to the present time a total of eighteen states, have enacted legislation relating to the sale and use of methyl alcohol, and the greater number of these states, declare it unlawful to sell products intended for the use of man, either for internal or external purposes, which contain methyl alcohol or wood spirits. Several states define a drug or a food as being adulterated, if it contains any methyl or wood alcohol. Little or no attention has as yet been given to the toxicity of methyl alcohol by absorption and apart from the several provisions included under occupational intoxications, no legislation has been noted that is designed to restrict or discourage the use of methyl alcohol in confined places.

Legislation designed to prevent the misbranding of drugs and of foods, while of comparatively recent origin, is already showing evidence of variance and vagaries. Some effort has been made, in connection with Public Health Bulletin No. 56, to show the variations existing in the requirements of the several state laws, but these variations are so well known to manufacturers and others who attempt to do an interstate business, that it will not be necessary to do more than call attention to them at this time.

The need for greater uniformity in state legislation on matters relating to public health, has been discussed repeatedly and several organizations, notably the American Bar Association, are making consistent efforts to bring about greater correlation in the statutes of the several states. The newly organized National Drug Trade Conference, gives promise of developing into a clearing-house for legislation relating to the several branches of the drug-business and incidentally, therefore, to the laws relating to the manufacture, sale and use of poisons and habit-forming drugs. From every possible point of view the development of such a clearing-house would be of advantage to all concerned and it should be encouraged by the members of the several organizations interested. The consistent censoring of proposed drug legislation, by members of a representative body, in which all branches of the trade have a voice, would serve to eliminate from our state laws much of the provincialism so evident at the present time. In conclusion it may be asserted that, if laws relating to pharmacy could be designed on a broader basis, they would serve to provide ample protection for the health and welfare of the public, and yet avoid many of the objectionable requirements which tend to hamper trade and unduly interfere with the conduct of legitimate business.

DISCUSSION.

Dr. Beal said that Mr. Wilbert had called very emphatic attention, in a very successful way, to one of the crying evils of the day, and to the fact that pharmacists in the past had operated upon too narrow lines, and said that by their failure to really establish a series of laws which would be a protection to the public, while at the same time they gave satisfaction to the pharmacists themselves, that they had been laying up trouble for themselves. The time had come when it was necessary to face about, and pharmacists should remember that their own best interests would be conserved by looking after the best interests of the public. He thought this matter should be brought to the attention of the National Drug Trade Conference, with the recommendation of this Section—or the recommendation of the Council—that an attempt should be made to draft some general form of legislation that would be sufficiently comprehensive, and at the same time provide an effective remedy for these evils.

Mr. Freericks expressed himself as having been very much impressed by the remarks of Mr. Wilbert, and that his own study of the various laws of the country pertaining to the subject of pharmacy, went to prove that, nearly always, there was some provision that, if tested, would be found invalid, if brought before the courts, that, while there was a general effort being made to improve such legislation, there was, usually, some local issue or condition, which induced the pharmacists of any given State to introduce into the draft of the bill presented, something that it should not contain. It had occurred to him—and he believed this was in line with a suggestion made in the paper just read—that it would be well to have, in connection with some association, a permanent committee, to which all intended legislation from the different States could be submitted for comment and suggestions. Because, no matter how many model laws might be drafted, there were always local conditions that would induce the “tacking-on” of certain provisions outside of the particular one considered in any single model draft. He felt sure, that if some central commission or committee were

charged with the business of looking after these things, it would be a great help—a "clearing-house," or something of that kind, as Mr. Wilbert had suggested.

Mr. Wallace thought that all must agree with the remarks of Messrs. Wilbert, Freericks and Beal, and suggested that a clearing-house had already been established in the National Drug Trade Conference, for this very purpose. It was true that, up to the present time, nothing but anti-narcotic legislation had been discussed before that body, as that was such an important subject that it necessarily occupied all the time the delegates could give to the question of legislation. The resolutions creating the National Drug Trade Conference, specifically provided that this work was the particular purpose of its establishment, which statement, he thought, would be borne out by the proceedings of the past year.

Mr. Freericks agreed, that it was true that the National Drug Trade Conference could work out the purpose indicated by the writer of the paper.

MANUFACTURE OF ABSORBENT COTTON.

As a general proposition absorbent cotton cannot be economically manufactured on the small scale, as the operation requires technical experience, special apparatus and a plant representing large capitalization. Some manufacturers, so-called, eliminate the preliminary manufacturing operations and buy the amount of absorbent cotton they may need, and use it as "raw material," preparing from it the various antiseptic cottons or specialties by their particular formulas. On the commercial scale the following outline represents the steps usually followed by the average manufacturer: The fat is first removed from the cotton by prolonged boiling under pressure with a solution of sodium hydrate or of an alkaline rosin-soda soap solution, and thorough washing with soft water. The cotton is then bleached by immersion in a clear solution of chlorinated lime, the latter being removed by one of several methods. One method consists in profuse washing with water, treatment with very dilute hydrochloric acid, immersion in a bath of sodium hyposulphite to remove the liberated chlorine, and addition of stearin soap. This reacts with the hydrochloric acid still retained by the cotton, stearic acid being liberated, this imparting to the cotton the peculiar "crunching" between the fingers when handled, a quality some users demand. This "crunching," however, may be removed by treatment with a very dilute solution of sodium bicarbonate. If desired, the absorbent property of the cotton may be destroyed by rinsing the material in a solution of alum. To secure a uniformly and satisfactory product thorough and copious washings with water after all operations must be rigidly observed.—*The Pharmaceutical Era*.

Section on Education and Legislation

Papers Presented at the Sixty-First Annual Convention

A SUGGESTION OR TWO.*

JOHN M. LINDLY, PH. G.

The lines of education are not fixed, but are alterable. Changes, additions and improvements are made as the signs of the times may indicate. What may have been regarded as of minor importance in one generation, may be considered of prime importance in the next, or *vice versa*.

Educators may outline a course of study which they regard as ideal, as including all the essentials, as meeting the demands of the age,—but the finished product, the student, when he steps out into the world, may find that he does not fit into place in its affairs as easily as he had anticipated, and the public also discovers something lacking in him.

At the recent meeting of the Iowa Pharmaceutical Association, the list of queries contained the following question:— “Should not our Colleges of Pharmacy insist that their graduates be better prepared as business men, so that at least the ordinary operations of charging, crediting, posting and making-out a bill may be understood?”

Such an implied criticism was common enough ten years ago, and is asked with more insistence to-day and there must be some reason for asking the question, as the list of queries was prepared by a member of the State Board of Pharmacy.

If the student, on leaving school, goes into business for himself, a knowledge of bookkeeping is absolutely necessary. If he becomes a clerk, which most do at first, such a knowledge is almost equally important. If he does not possess knowledge of such matters his employer is displeased, criticises him as incompetent and condemns the institution that has conferred its degree upon him.

But the educator may say, that bookkeeping, or a knowledge of business, is not a part of a course in Pharmacy; that the student is supposed to have obtained such knowledge in the public school, or in some commercial college. However, if he has not obtained such knowledge in the public school, or been trained in a business college, our student in pharmacy enters into the exercise of his profession with but one hand trained, the other untrained and awkward. And, of course, his progress cannot be as smooth as he or his employer expected. The employer of a Graduate in Pharmacy expects to receive the assistance of a skilled man, an

*Read before the Section of Education and Legislation at the Nashville Meeting, August, 1913.

all-around, competent man. As Pharmacy, nowadays, is more of a commercial or business matter than formerly, as compounding has become a less prominent feature in it, the College of Pharmacy that desires to turn out its graduates fully prepared for the business of Pharmacy, must see to it that its graduates have some knowledge of the principles and rules of business. If the student has already secured such knowledge, well and good. But if he has not such knowledge, the College of Pharmacy should afford him the opportunity of acquiring it. A few lectures on the principles of business, and on the essentials of book-keeping, delivered during the closing weeks of the school year, to both juniors and seniors, will prepare them to meet the customer at the counter, fit them to do business with business-method and make them ready to turn their knowledge of pharmacy,—which has up to the present time only fitted them for the laboratory,—into coin, that alone buys bread and butter and keeps the body and soul together.

There comes to mind, as an illustration, the case of a preacher who was a good-looking young man, pleasant and agreeable, a graduate of a prominent theological seminary, but whose success was very indifferent, owing to his great disregard for the rules of elocution. This defect was noticeable in emphasis, and particularly in inflection. A fine sentence was often spoiled, by the use of inflections the very opposite of that which should have been used. His mistakes were like discords in music. His hearers were offended by his false rhetoric and did not endure it long. When asked if the theological seminary from which he graduated, did not instruct their students in elocution, he replied that it did not; that the student was supposed to have received such instruction in the preparatory college.

On being interrogated as to whether he had taken such instruction in college, he replied that the course was optional and, as he had not been interested in it, he had not taken it. Thus he had been allowed to pass through both the college **and the theological seminary**, without having studied or having received any instruction in the art of elocution, or public speaking. When he graduated from the seminary, he was supposed to be prepared for the career of a public speaker, but he was not. A public speaker, yet he had no knowledge of the art of public speaking! The art by which it was expected he would make use of the knowledge acquired during his many years of study *had been entirely neglected*. The ostensible preparation of young men for the career of public speaking, that does not include any instruction in the art of oratory and rhetoric is a glaring absurdity.

The College of Pharmacy that will most effectually serve the patrons and public, is that one which provides that its students, is not previously so instructed, shall receive proper instruction in the principles and rules of commercial transactions, in order that its students shall be prepared for the business of pharmacy as well as for the laboratory.

DISCUSSION.

Mr. Anderson thought this paper a very valuable one, and one eminently worthy of consideration. The subject touched upon, was one that had agitated the retail drug-trade for many years, where it was felt that the graduates of colleges should be better versed in the business side of pharmacy, and that it was the duty of the colleges of pharmacy to so prepare

their students. He believed that it was mainly through the agitation of the retail drug-trade, and the presentation of such papers as this, that the colleges had been stimulated to give more attention to the commercial side of pharmacy, that, to-day, there were very few colleges in the country that did not make some provision for this form of instruction. The Pharmaceutical Syllabus, which was in process of making, made a particular point of this, and outlined a certain number of hours that must be devoted to the teaching of commercial subjects, such as bookkeeping, making-out bills, banking, the value of notes, etc., all of which were in use in the every-day practice of pharmacy. This course, was, of course, supposed to embrace, also, everything that pertained to the conduct of a drug-store, such as the handling of customers, and of stocks, buying and selling, etc. He believed in the future the pharmacists of the country might not only expect, but also might rely upon the fact, that the graduates from the various colleges,—particularly those who took up the Syllabus in the serious manner they should, and abided by its regulations—would come to them better prepared in the duties of this important and essential part of pharmaceutical education.

THE TREND OF MODERN MEDICINE.*

RUFUS A. LYMAN, DIRECTOR OF THE SCHOOL OF PHARMACY, UNIVERSITY OF
NEBRASKA, LINCOLN.

In these days of rapid progress in both the fundamental and the special medical sciences, one hesitates to prophesy as to what the future may bring. Being in close touch with the drug men of my own state, Nebraska, I hear the complaints of the rank and file of the profession, and am forced upon every occasion to play the part of the optimist. The most common lament is, that pharmacy is a lost cause. Nebraskans are not alone in this belief for if I remember rightly, in the last five years, I have heard some half-dozen papers read by men of prominence in the National Association, urging druggists to take up urinalysis, bacteriology, and, even, first aid to the injured, as side lines, in order that they may have something of a professional nature to do. Of course, as usual, and as it must always be, the pharmaceutical manufacturer and the physician that prefers to prescribe the manufacturer's preparations rather than those made locally, come in for their share of the blame for the condition of things. But now, there is advanced another and a more serious cause, namely, that preventive medicine, serum therapy, and therapeutic measures, other than with the use of drugs, will make professional pharmacy superfluous. With this in mind, perhaps it is worth our while, for a moment, to glance over the field and note what physiological basis, if any, drug therapy has, and what we may expect of it in the future.

We are living in an age of medical fads. Like mushrooms, they appear in a night, mature in a day, and disappear as quickly and as silently as they came. Perhaps chief among the faddists, are those who have placed upon the nervous mechanism an undue importance,—maintaining that the various abnormal physiological conditions, that we find in disease, to be due to so-called nervous influences, and to be rectified thru some re-adjustment, mechanical or otherwise, of the nervous system, or of some structure in close relation to that system.

Such ideas are untenable, if we but stop to study the physiology of the cell

*Read by title before Section on Education and Legislation at Nashville Meeting, 1913.

or of the highly organized animal. In the single-celled animal, there occur all the usual physiological phenomena such as digestion, absorption, assimilation, excretion, reproduction,—in fact all the physiological processes necessary for the maintenance of life, and the preservation of the species, without the existence of a nervous system, or anything suggestive of it. In more highly organized animals, we have the appearance of a nervous system, which reaches its highest development in man. While the nervous system is necessary in our complex mechanism, for the production of quick motor-reactions, the fact should not be lost sight of, that the functions of the various organs of the body are regulated or correlated thru the action of chemical bodies and are primarily independent of the central nervous system. To illustrate what I mean, I shall discuss a few important tissue-products which are typical examples of chemical bodies producing physiological correlations.

The simplest, at least the most familiar example of a chemical correlation in the body, is the relation which exists between the carbon dioxide tension in the blood, and the activity of the respiratory center. It is now pretty definitely settled that while carbon dioxide may not be the only factor, it is certainly the chief factor in initiating the inspiratory act. At birth, the foetal circulation is interrupted, thru the detachment of the placenta. The carbon dioxide which is formed in the infant's body, by the tissue metabolism, can no longer be eliminated thru the maternal circulation. It therefore collects in the blood, until a sufficient quantity is formed to stimulate the respiratory center, and produce the first inspiration, and its constant formation maintains respiration thereafter. While the quantity of oxygen in the blood may vary greatly, without influencing the activity of the respiratory center to any marked degree, an increase of 8 percent of the carbon dioxide content of the blood, will increase the amount of air inspired 100 percent.

Largely thru the efforts of the Russian physiologist, Pawlow, and his pupils, and the English physiologists, Bayliss and Starling, many chemical correlations are known to exist in the digestive mechanism. For example, it has been thought that the activity of the pancreas was due largely to the effect of impulses reaching it thru the central nervous system, reflexly or otherwise. Now, it has been shown that the pancreatic cells become active, and produce their secretion, only when a definite chemical body reaches them thru the blood. This chemical body is known as "secretin" and is formed from "prosecretin," a product of the intestinal mucosa, and the hydrochloric acid coming into the intestine, from the stomach. The "secretin" enters the blood and, thru it, reaches the pancreas, where it produces a profuse flow of pancreatic juice. Again, the pancreatic secretion contains a powerful proteolytic enzyme known as "trypsin." "Trypsin," as such, does not exist in the secretion, as it comes from the gland but a zymogen, "trypsinogen," does. In the intestine, "trypsinogen" comes in contact with a body formed in the intestinal mucosa, known as "enterokinase" and, thru its action, "trypsinogen" is converted into "trypsin." Not only are there chemical bodies, elaborated in the digestive glands, which have a pronounced effect upon their own activities, but certain glands produce, in addition, internal secretions, containing substances which have a marked effect upon metabolism in gen-

eral. The pancreas is one such. It has been shown that the internal secretion of this organ contains a body, which enters and circulates in the blood and is absolutely essential for the proper metabolism of sugar.

Of the ductless glands of interest in this connection, the thyroid and the suprarenals are the most important. The physiologically active body in the thyroid secretion, is a combination of iodine with a protein molecule. As is well known, the absence of this compound in the infant, results in a lack of development in every tissue in the body, and a lessened mentality. If the thyroid is removed, or the normal secretion is interfered with thru disease of the organ, a series of symptoms follow which ultimately prove fatal. These conditions may be prevented, either by the intransplantation of a normal gland, or by the constant administration of the fresh, or the prepared gland. Epinephrine, a basic substance, is the active constituent of the suprarenal and is supplied constantly to the blood. This body is essential for the maintenance of tonicity in the muscles,—skeletal, vascular, and heart. Removal of the gland, results in death in a very short time.

A most interesting set of correlations, is found to exist in the reproductive organs. The general effect upon metabolism, of the removal of the male gland, is too well known to need discussion here. A similar effect is observed in the female, after removal of the ovaries, a more important relation, however, has been proven to exist between the ovaries and menstruation, and between the ovaries, uterus and the mammary glands. It has been shown that menstruation is brought about by a chemical substance, formed in the ovary at certain times, which stimulates the mucous membrane of the uterus to greater activity, resulting in increased growth. This process is not interrupted, even when all nervous connections with the organs concerned are severed. Likewise, the mammary glands atrophy, with the extirpation of the ovaries. There is no doubt but that the secretion of milk is profoundly influenced by nervous impulses. On the other hand, Bayliss and his pupils have shown, that the growth of the mammary gland, which takes place during pregnancy, is due to a chemical body which is formed in the foetal body *in utero*. This body enters the maternal circulation, and stimulates the growth of mammary tissue or causes the formation of milk. These experiments using rabbits, macerated the foetal bodies, and made a watery extract. By introducing this extract into the circulation of non-pregnant rabbits, they were able to cause an increased growth in mammary tissue and ultimately the formation of milk.

While I have mentioned some of the more important chemical correlations which are known, there are many others, and it is not unscientific to presume, from what we already know, that there are many more, the chemical and physiological nature of which we do not know. From our present knowledge, it would appear that the fundamental physiological processes are due to chemical reactions of a more or less complex nature, and that the nervous system is a system that has become specialized as a necessary convenience, rather than as an absolute necessity in the production of those processes.

Ehrlich, and many others, have raised the question that if there are chemical bodies elaborated within the animal body capable of producing such profound

physiological changes, why is it not possible, or even probable, that there are many substances, which are normally not a part of the body, which may produce similar changes in whole or in part. The utopian dream of medical science, is to find a set of such substances with which the physician can control the functions of the body at will. Ehrlich believes there are many such bodies, and, to me, it is a significant fact, that he who has done so much work in the field of immunity, has practically deserted the field of serum therapy, in order to devote the best years of his life to the study of the physiological action and therapy of drugs. At present, his efforts are being directed toward the discovery of drugs which act as specifics in certain diseases, such as quinine in malaria. While his discovery of the specific action of the arsenic compounds in syphilis, is an epoch-making discovery, we may be sure that it is only a beginning of the revelations which the future has in store. The establishment by our leading universities, of laboratories for the experimental study of drug therapy, is a most potent proof of its importance.

Viewing the future of medicine from the standpoint of how physiological phenomena are produced in the body, knowing to some extent how these phenomena may be modified by the intra- and extra-corporeal products, and realizing the work to be done in connection with the collection, preservation, preparation, standardization, and dispensing of such products for therapeutic use, it seems hardly proper to consign professional pharmacy to the superfluous science class.

HEALTH IN GEORGIA.

What North Carolina is doing and what Georgia is not doing for the health of their respective populations makes a suggestive contrast. The *Progressive Farmer*, of Raleigh, tells us, in an editorial The Constitution reproduces, that in a state-wide campaign against typhoid the state furnishes the vaccine free and the county the services of physicians free. The process extends through the regulation three treatments.

It is merely a matter of arithmetic that in course of time, and a comparatively short time, North Carolina will subjugate the scourge of typhoid. The vaccine is about as absolute a preventive as cowpox vaccine for smallpox.

Georgia's attitude toward disease shows in discouraging contrast. It is not the fault of the State Board of Health. The hands of this body are tied by lack of authority and still greater lack of money. It is willing and ready to practice the conservation of human life on a large and habitual scale, but it can do nothing until machinery is placed at its disposal.

Georgia has long enough been neglectful of her greatest asset, human life. It is the only state in the Union without a system for collecting vital statistics. The Legislature that assembles to-day can perform no service of a more constructive nature than by enacting the vital statistics and the public health bills.—*Atlanta Constitution*.

College and Society

THE PREAMBLE TO THE CONSTITUTION OF THE CINCINNATI BRANCH.

"The American Pharmaceutical Association is recognized the world over as the Trustee of true Pharmacy in the United States, and should in our judgment include among its membership every real Pharmacist, and everyone interested in the advancement of Pharmacy, and its allied branches. Its lofty aims and ideals, its work in the interest of Pharmacy and for the proper recognition of Pharmacists entitles it to a more general support. The time has come in its history when Pharmacists and those interested in Pharmacy should be brought into a more direct and frequent touch with each other under its guidance, so that its earnest endeavor, and the spirit of advancement prevailing within its ranks be more generally appreciated, and its store of knowledge more readily disseminated. In order to make effective these present-day needs, the members of the American Pharmaceutical Association residing in Cincinnati and its vicinity have resolved to organize, and do now organize to maintain a permanent branch thereof, and for that purpose adopt Constitution and By-Laws."

A large party, consisting of the members of the City of Washington Branch, American Pharmaceutical Association, and their guests, visited the Experimental Farm of the Department of Agriculture at Arlington, Va., in charge of Dr. W. W. Stockberger and several assistants, one day last month.

The party was carefully shown through that part of the farm devoted to the drug-plant experiments and had explained to them the nature and progress of the investigations being carried on there. Dr. Stockberger very carefully discussed the folly of many of the recently-advertised get-rich schemes connected with plant culture, and told of many interesting and peculiar inquiries received at the Department of Agriculture concerning plants and their development.

Later the party was taken to the farm

buildings where experiments are being carried on in connection with the production of rose water.

The Indiana Pharmaceutical Association has elected as officers for the ensuing year:—

President—Ernest W. Stahlhuth, Columbus, Ind.

First Vice President—Charles Gelolin, Nashville, Ind.

Second Vice President—W. S. Margowski, Delphi, Ind.

Third Vice President—A. J. Fraizer, Muncie, Ind.

Treasurer—Frank H. Carter, Indianapolis, Ind.

Secretary—Wm. F. Werner, Indianapolis, Ind.

Executive Committee—E. W. Stucky, Indianapolis, Ind.; D. H. Houks, Goshen, Ind.; J. T. Shandy, Terre Haute, Ind.

THE COLLEGE OF PHARMACY OF THE STATE UNIVERSITY OF IOWA.

IOWA CITY, IOWA.

The baccalaureate address to the graduates of the University, was given by the Reverend Charles Richmond Henderson, D. D., of the University of Chicago, Sunday afternoon, June 14th. On the evening of the same day occurred the annual Social Service meeting, under the auspices of the U. N. and U. W. C. A. This meeting was addressed by the Reverend Effie McCollum Jones, pastor of the Universalist Church at Waterloo.

Tuesday of Commencement week was Alumni day and various classes held their reunions. In the afternoon a series of "stunts" were carried out, as well as a game of base ball between an alumni team and the "Varsity," in which the latter team was the winner.

The twenty-eighth annual commencement of the College of Pharmacy occurred Wednesday, June 17th, together with the commencement exercises of the eight other Colleges of the University. The address was given by the Hon. Alexander MacDonald, LL.D., managing editor of the Toronto Globe, on the subject of Internationalism and the University. Two students received the second degree in Pharmacy, that of Pharmaceutical Chemist. They were Homer D. Long, Ph. G., 1911, and Thurston J. Long, Ph. G., 1913. The degree of Graduate in

Pharmacy was conferred upon the following people: Herbert Frederick Doden, Wilton, Junction; Leslie Knapp Fenlon, Clinton; Robert C. Hahn, Muscatine; Raymond C. Harvey, Guttenberg; Francis P. Hess, Lone Tree; N. Reno Hohmann, Iowa City; Clyde E. Jacobs, Iowa City; Edward Kiedaisch, Keokuk; John Frederick Keidaisch, Keokuk; Walter E. Palmer, Murray; Carl C. Powers, Murray; John Fred Babe, Marengo; Harry E. Rutenbeck, Lost Nation; Maud Wieland, Red Oak.

The Dean Teeter's prize of membership in the American Pharmaceutical Association for recognition of organic drugs was awarded to H. M. Doden, of Wilton. Mr. Doden also attained the highest rank in Practical Pharmacy for the Senior year, thereby winning membership in the Iowa Pharmaceutical Association offered as prize by Prof. Zada M. Cooper.

Prof. Kuever's prize of a year's subscription to the JOURNAL OF THE AMERICAN PHARMACEUTICAL ASSOCIATION offered to the Junior student attaining highest rank in Practical Pharmacy was awarded to L. T. Dyk, of Orange City.

Among the Alumni and former students of the College who were in the city for the Commencement festivities were J. M. Lindly, '89, of Winfield; Edith Seymour, '05, of Fort Dodge; J. A. Pierce, '09, of Denver; B. H. Davis, '08, and wife, of Onawa; C. L. Kettellwell, ex-'91, and wife, of Carson.

The College was represented at the annual convention of the State Pharmaceutical Association held at Burlington the second week of June, by Dean W. J. Teeters and wife, Professor Zada M. Cooper, Professor R. A. Kuever and Dr. C. S. Chase. Both Professor Kuever and Dr. Chase appeared on the program. Mr. E. L. Boerner, former Dean of the College of Pharmacy, and Professor Emeritus attended also.

The marriage of Professor R. A. Kuever and Miss Ruth Hindman occurred at the home of the bride's mother at Iowa City at 8 o'clock on the evening of June 20th. Only relatives and intimate friends were present. Professor and Mrs. Kuever will spend a month in the West and, after their return to Iowa City, will be at their new bungalow home on the West Side.

On the evening of June 13th, Dean and Mrs. Teeters entertained the members of the Senior class at their home on the West Side.

KENTUCKY PHARMACEUTICAL ASSOCIATION.

The annual convention of the Kentucky Pharmaceutical Association was held at Lexington on June 16-17-18, and, after a pleasant and successful meeting, elected the following officers for the ensuing year:—

Leon Evans, Mayfield, President; W. H. Tibballs, Somerset, First Vice-President; Miss Alice Caden, Lexington, Second Vice-President; George Morland, Brandenburg, Third Vice-President; J. W. Gayle, Frankfort (re-elected), Secretary, and V. Driskell, Carrollton, Treasurer. Executive Committee: R. S. Berryman, Versailles; William J. Johnston, Mayfield, and G. R. McGinnis, Louisville.

Cerulean Springs or Dawson Springs will be the next year's meeting place, the exact place not having been determined upon.

The following list of names, from which to select a member of the State Board of Pharmacy Examiners was agreed on to be presented to the Governor, who annually makes the appointment from the members of the State Pharmaceutical Association: Dr. C. Lewis Diehl, of the Louisville College of Pharmacy; Simon N. Jones, Louisville; C. J. Clark, Paris; R. S. Berryman, Versailles, and Charles Lordier, Ashland. Dr. Diehl is at present a member of the board.

Mr. Henry P. Hynson, of Baltimore, was a special guest of the Association and gave many interesting and instructive talks out of, and during the meetings, besides winning the hearts of the men as well as the ladies.

At the last session the members had the pleasure of hearing Dr. L. F. Kebler, Chief, Drug Division, Bureau of Chemistry, U. S. Department of Agriculture, who gave a most interesting discourse on the work done by his department, in enforcing the Pure Food Laws, etc.

Six new applications for membership to the A. Ph. A. were received.

MARYLAND PHARMACEUTICAL ASSOCIATION.

The annual meeting of this Association was a lively one, in which Professors Charles E. Caspari, Jr., and J. F. Hancock were in active opposition to one another on legal questions involving pharmacists. Dr. Caspari criticised the action of some pharma-

cists, in being obstructive of the work of the State Board of Health. Dr. Hancock defended the action of the druggists.

President George M. Beringer addressed the convention, and made a felicitous address touching upon the importance of fraternal feeling among the druggists of the state and nation.

The Association elected the following officers for the ensuing year:—

J. D. Leary, President; George A. Bunting, Eugene Hodgson and Henry Howard, First, Second and Third Vice Presidents, respectively; E. F. Kelly, Secretary, and S. Y. Harris, Treasurer; Members of the Executive Board, J. Fuller Frames, David P. Schindel and H. G. Wendel; Pharmacy Commissioners, one to be selected by the Governor, D. R. Millard, J. E. Hengst and H. C. Spetzler.

Thirty new members were elected, bringing the total up to about 450.

MISSOURI PHARMACEUTICAL ASSOCIATION.

The thirty-sixth annual meeting of the Mo. Ph. A. and the twenty-third annual convention of the Mo. Ph. Travelers' A. met at Pertle Springs, Warrensburg, June 16-19. The women do not have an auxiliary but have been attending the meetings since the one at Brownsville, in 1886. They have an entertainment program of their own and look after the children with games and prizes.

More retail druggists attended the meeting this year than usual, but the number of travelers was not as large as last year.

The Stevens Bill (H. R. No. 13305), intended to regulate retail prices and stop cutting, was the subject of much discussion and was endorsed by the Association.

The Kansas City R. D. A. introduced a resolution, censuring those manufacturers who give jobbers a special discount. After an extended discussion, the resolutions were finally adopted.

The reading of papers and discussions that followed occupied much of the time of the seven sessions. Some of the papers were illustrated with specimens and accompanied with demonstrations which added to their practical value and the attention given them. The exhibits were confined to pharmaceutical preparations, articles of historical interest, soda fountain syrups and similar goods. These exhibits have been an annual

feature of the Mo. Ph. A. for some years past.

The Association added thirty-seven new names but will drop more than twice that number. A net membership of over 700 will remain. The by-laws were amended so that delinquents may be dropped after one year, instead of waiting three years as heretofore.

The third Tuesday in June, 1915, was the time and Pertle Springs the place selected for the next meeting. The Association has already convened fourteen times at Pertle Springs. The decision to return next year was unanimous.

The new officers are: O. J. Cloughly, St. Louis, President; Hon. Louis Grother, Cole Camp, Honorary President; J. A. Trimble, Butler, First Vice-President; John M. Hawkins, East Prairie, Second Vice-President; H. D. Llewellyn, Mexico, Third Vice-President; William Mittelbach, Boonville, Treasurer; Dr. H. M. Whelpley, St. Louis, Permanent Secretary; Jacob Lieberstein, St. Louis, Assistant Secretary; F. W. Robinson, Warrensburg, Local Secretary.

Council: Ed. G. Schroers, St. Joseph, Chairman; R. A. Davidson, Essex, Vice-Chairman; Professor D. V. Whitney, Kansas City, Secretary; Alfred W. Pauley, St. Louis; Joseph Clinkenbeard, Lamar; with the President, Secretary and Treasurer, ex-officio.

President O. J. Cloughly announced the following chairmen of committees: Deceased Members, Fred. R. Dimmitt, Kansas City; Entertainment, George R. Gibson, St. Louis; Drug Adulterations, Minnie M. Whitney, Kansas City; Exhibits, J. A. Koppenbrink, Higginsville; Ladies' Entertainment, Mrs. H. M. Whelpley, St. Louis; Legislation, F. H. Fricke, St. Louis; National Formulary, Carl T. Buehler, St. Louis; Membership and Attendance, R. A. Davidson, Essex; Papers and Queries, Professor Francis Hemm, St. Louis; Trade Interests, J. A. Kinder, Cape Girardeau; Transportation, George M. Scheu, St. Louis; U. S. Pharmacopœia, William Mittelbach, Boonville; Welcome, R. A. Doyle, East Prairie; Candidates for Board of Pharmacy, Dr. Otto F. Claus, St. Louis; Pharmaceutical Assay Processes, F. H. Fricke, St. Louis; Delegation to A. Ph. A., Charles E. Zinn, Kansas City; Historian, Leo Suppan, St. Louis.

Papers as follows were read and discussed:

1. French Folk Medicine, by J. F. Llewellyn.
2. Can We Improve the Missouri Pharmaceutical Association?, by Dr. H. M. Whelpley.
3. Future for Retail Pharmacists, by O. J. Cloughly.
4. Timely Topics, by Dr. H. M. Whelpley.
5. Odd Prescriptions (illustrated with specimens and methods of filling unusual prescriptions), by Professor D. V. Whitney.
6. Missouri Prehistoric Mortars and Pestles (illustrated with several specimens), by Dr. H. M. Whelpley.
7. Compilation of Poisons Employed; taken from "St. Louis Coroner's Records"—from 1904 to 1913, by Professor Francis Hemm.
8. The Missouri Pharmaceutical Association 1889 Meeting, by Dr. H. M. Whelpley.
9. Some Preparations of the U. S. P., by H. D. Llewellyn.
10. The Missouri Pharmaceutical Travelers' Association, by Dr. H. M. Whelpley.
11. Bacterial Vaccines, Sera and Phylacogens, by John B. Wood.

PENNSYLVANIA PHARMACEUTICAL ASSOCIATION.

The adoption of a draft of a proposed anti-narcotic law and the recommendation to the incoming Committee on Legislation that it prepare drafts of a heroin and an itinerant vender's bill, featured the action of the Pennsylvania Pharmaceutical Association which held its thirty-seventh annual meeting at Buena Vista Spring, Franklin County, Pa., June 23, 24 and 25. From the standpoint of action taken; of the value of the papers read and discussed and of the enjoyable entertainment features, the meeting was one of the most successful ever held by the Association. The attendance was slightly below normal, but the reports of committees and officers indicated that the past year had been a particularly successful one.

This was particularly true from the standpoint of membership, for Chairman William H. Knoepfel of the Committee on Membership announced that 130 names had been added to the list at the low cost of \$18. In 1911, it cost \$780 to secure 428 members; in 1912, the cost was \$450 to get 149 members, and in the following year, 38 members were added at no cost other than postage. The loss by death last year was 16 and by resignation and non-payment of dues, 28.

The need of a heroin law was emphasized when members of the Pennsylvania Pharmaceutical Examining Board declared that the

sale of this drug in the stores of Pennsylvania was growing to an alarming degree with the corresponding decrease in the sales of cocaine, due to stringent State and Federal legislation. The Committee on Legislation brought in a recommendation that an amendment, taking care of heroin, be made to the Cocaine Law. But it was subsequently decided to frame a separate law on heroin, putting heroin in the same class with cocaine. At present, this drug is classed as a poison and can be sold when the sale is registered. Under the proposed law, it can be sold only on the prescription of a physician, such prescription not to be renewed.

In a most comprehensive report, Chairman Charles E. Vanderkleed of the Committee on Drug Market stated that the character of the drugs and chemicals submitted for sale in Pennsylvania during the past year were a great improvement over those of previous years, and that cases of adulteration were very scarce. He proved these statements by statistics gathered among pharmacists and chemists throughout the State.

The Association endorsed the provisions of H. R. Bill 13,305, known as the Stevens Bill, and elected Caswell A. Mayo, President-elect of the American Pharmaceutical Association, an honorary member of the Association. He is a classmate of the retiring President, Richard H. Lackey, of Philadelphia. Following a recommendation by the President, the Association also went on record as approving an amendment to the Act of May 24, 1887, providing for the printing of an antidote on the label of commonly-used poisons.

The Committee on Papers and Queries, of which Mr. Fred. J. Blumenschein was Chairman, with the following associates, Prof. J. W. Sturmer, P. Henry Utech, Mrs. Bertha L. DeG. Peacock, and Prof. E. Fullerton Cook, issued the following comprehensive list of subjects for papers to be read before the meetings:—

LIST OF QUERIES.

- 1—Pharmacy in America from 1814 to 2014, views retrospective and prospective, are wanted.
- 2—It is said that if the principles governing the Pennsylvania Farmers' Grange were adopted by organized pharmacy improved conditions would soon prevail. An exposition of these principles is desired.
- 3—It is claimed that the bane of habit-forming drugs will adjust itself if new recruits are not formed. An investiga-

- tion as to how habitues of narcotic drugs are produced is desired.
- 4—How does the laity learn the use of the newer synthetic remedies?
 - 5—Has the pharmacist advanced his retail prices to meet the "high cost of living"?
 - 6—What should be the wages of a college educated drug clerk?
 - 7—Wanted: A plan for a "pure drugs" advertising campaign to be conducted by county or state associations.
 - 8—Wanted: A plan for a co-operative analytical laboratory.
 - 9—Is it ethical to ask physicians to send their patients to lunch-counter drug stores to have prescriptions compounded? Would you go to a restaurant for a remedial agent?
 - 10—Can pharmacists do anything to bring about the teaching of pharmacy and chemistry in medical schools?
 - 11—Wanted: The best method for obtaining new members.
 - 12—Is the stock of expensive chemicals required to conduct a general prescription business warranted through profit or advertising?
 - 13—What percentage of profit in advance should be figured on the cost price of expensive ingredients in a prescription ordered in unusual quantities?
 - 14—Do pharmacists as a rule dispense U. S. P. lime water?
 - 15—Magma Magnesiae: The manipulation of the N. F. process is somewhat tedious. What has been your experience with it?
 - 16—Papers dealing with the prescription nomenclatures of different nationalities are wanted.
 - 17—Since the registration of some "poisons" is compulsory, would it be advisable to curtail the sale of small quantities of such articles?
 - 18—What is your definition of a poison?
 - 19—Is there any particular advantage in using pepsin of higher proteolytic power for making the various official preparations?
 - 20—What is your best selling "own make" preparation? Will you give the working formula and method of procedure?
 - 21—Describe any special window display which you have made and which has proven a trade winner.
 - 22—Can you suggest any method for improving either process or product of any U. S. P. or N. F. formula?
 - 23—How many hours per day and how many hours per week would appear proper for a registered pharmacist to be employed?
 - 24—Does the state law which prohibits the sale of cigarettes to minors also include the sale of medicated or tobaccoless cigarettes?
 - 25—What is your experience as agents with the so-called "proprietary" lines of non-secret remedies? Is there any advantage in selling your own goods?
 - 26—Have you a legal right to sell a "poison" to a minor? Who is responsible in the event of accidental use of such poison?
 - 27—Is it good practice to pour into the bottle of a customer more of a substance which may already be in it, even though it bears your label?
 - 28—What has been your experience with the Salol coating of pills?
 - 29—Glutoid capsules: Their use and methods of preparation.
 - 30—Is there any real objection to filtering Brown Mixture? Does filtering remove any valuable constituent?
 - 31—Is there any objection to replacing Solution of Potassium Arsenite with Solution of Arsenic Chloride when the former is prescribed with Syrup of Ferrous Iodide or Tincture of Ferric Chloride?
 - 32—Prescriptions; Attractive packages; Delivery; At what rate do you figure the cost of service in compounding?
 - 33—Should the pharmacist tell customers the nature of the "Fakes" which are advertised to the public through reading notices in the newspapers as bona fide drugs?
 - 34—To what extent can the pharmacists of this state compel the enforcement of the "Truth Advertising Law"? In what way are you aiding the police officials to rid your community of those stores that make a business of selling habit-forming drugs?
 - 35—Can you afford to permit a high-salaried prescriptionist to dispense soda water? Can you expect the public to believe the man is a trained pharmacist if they see him cleaning windows, mopping floors, etc.?
 - 36—Cameras and Supplies. Their value as trade builders.
 - 37—To what extent do pharmacists keep their drugs and chemicals in proper containers?
 - 38—Sodium Beta-Naphtholate. Literature regarding toxicity and antiseptic properties is wanted.
 - 39—Salable toilet articles and household remedies.
 - 40—Is it logical and is it wise for Pennsylvania Colleges of Pharmacy to reduce "the four-year practical experience requirement" for graduation in case of students who have completed a four-year high-school course?
 - 41—Should our pharmacy law embody a clause requiring the registration of pharmacy apprentices?
 - 42—What evils may be expected when the latitude permitted by the "Variation Clause" of the Pure Food and Drugs Act is understood?
 - 43—From the standpoint of the manufacturer, why should the "Variation Clause" permit variation, only in case a drug is not inferior to the official standard?

- 46—To what extent is Essence of Ginger sold in general stores, especially local option districts? Why should we not have a law prohibiting the sale of Essence of Ginger except on prescription?
- 47—Ownership of pharmacies by wholesalers. Who is most to blame for this?
- 48—Co-operation or competition. Which is best?
- 49—Stopping leaks in business.
- 50—The retail pharmacist and the traveling salesman. The retail pharmacist and the country newspaper.
- 51—The physician, the pharmacist and proprietary medicines.
- 52—The pharmacist versus legislation.
- 53—Does it pay country druggists to solicit business of dispensing physicians?
- 54—Is the prescribing of synthetics increasing or decreasing? Why?
- 55—To what extent is a preceptor under obligations to instruct his employes in practical pharmacy?
- 56—What benefit do you derive from belonging to and attending the annual meetings of the A. Ph. A.?
- 57—Outline the system you use in taking care of credit business.
- 58—Business plans I have successfully used.
- 59—The comical side of a serious business.
- 60—It has been proposed by a faction in the American Conference of Pharmaceutical Faculties to raise the pharmacy entrance requirements from one year of high-school work to two years. Is such a change desirable in Pennsylvania at this time?
- 61—Lloyd's Reagent; Fullers Earth; Kaolin: Behavior toward alkaloids.

The election of officers resulted as follows: President, Edgar F. Heffner, Lock Haven; First Vice-President, J. C. Peacock, Philadelphia; Second Vice-President, F. M. Siggins, Meadville; Secretary, David J. Reese, Philadelphia; Assistant Secretary, Lewis H. Davis, Philadelphia; Treasurer, F. H. E. Gleim, Lebanon; to the Executive Committee, Frank P. Streeper, Philadelphia; Local Secretary for the 1915 meeting, Louis Frank, Wilkes-Barre. It was decided to hold the 1915 meeting at Forest Park, Pike County, June 22, 23 and 24.

HONORARY DOCTORS OF PHARMACY.

In appreciation of invaluable services, unselfishly rendered in the interest of their Institution, or in recognition of highly meritorious work contributed for the advancement of Pharmacy and Allied Science and in ac-

knowledge of fruitful efforts directed toward the betterment of general education, the Board of Trustees of the University of the State of New Jersey have conferred the Honorary Degree of Doctor of Pharmacy, Ph. D. Honoris Causa, upon the following men, well known in the field of pharmacy and medicine:

Joseph P. Remington, Ph. M.
George M. Beringer, Ph. M.
Joseph Koppel, M. D.
Otto Raubenheimer, Ph. G.
Leon J. Lascoff.
Jacob Gutman, M. D.

The Pharmacist and the Law

WRITTEN CONTRACT FOR SODA FOUNTAIN—VARIANCE BY ORAL AGREEMENT.

In an action for the balance due on a soda fountain sold by the plaintiff to the defendant, the latter offered to prove by the plaintiff's agent and by the defendant, that coolers were to be installed in the cooler boxes, which coolers were to be of a given capacity made known to the plaintiff's manager and draftsman in Philadelphia at the time the contract was drawn. The defendant also offered testimony to show that there was to be installed a soda water apparatus capable of furnishing cool soda. The trial court refused both of these offers. It found that the defendant purchased the fountain, that it was installed in his place of business, that \$530 was paid on account, that the plaintiffs made an allowance of \$41.50, leaving a balance of \$563.50, that the orders signed by the defendant, together with the plan and letter of acceptance, constituted a complete contract which bound the defendant, and that no oral testimony could be admitted as to the capacity and installation of coolers. This was affirmed on appeal.

The contract between the parties was in writing; that is, the defendant signed an order and approved the plan, and the order was accepted by the plaintiff. The order was directed to the plaintiff, and requested the delivery of the "following described soda water apparatus and appurtenances," and then followed a description of the structure,

with a note that, if it was for counter service, then there were to be additional details. These details appeared in the order under the title "counter service details," in which the following appeared: "One cooler box, no coolers with milk pump and 1-3 gal. can in centre, surrounded by four crushed fruit jars, as per plan." It was not denied that the defendant furnished all that he was required to do according to the writing, but the defendant argued that the contract was incomplete, and that he was entitled to offer oral testimony to show what was required to complete it. It was held that the contract, as written, was complete. The defendant might have expected more, and he might, during the negotiations, have contracted for more, but, when the contract was put in writing, that expressed the result of the negotiations, and oral testimony was not admissible to vary its terms.

Green v. Watts, New Jersey Supreme Court, 90 Atl. 667.

CASH COUPONS—ILLEGAL CONTRACTS.

An offer by the proprietor of a drug store to give a piano at the end of a designated period to any person who shall present to him the largest amount of cash coupons, representing purchases from the drug store, is equivalent to maintaining a lottery; and if the druggist purchased the piano from a dealer who agrees to furnish the literature and advertising necessary to carry out the scheme, such dealer cannot recover the price of the piano and the advertising, inasmuch as it was an illegal contract and therefore not enforceable.

Main v. Mackey, 39 Pa. Co. Ct., 589.

CONSTRUCTION OF EMPLOYER'S LIABILITY POLICY.

A drug company employer's liability policy, stated that the premium of \$113.90, placed therein, was based on estimated upon data furnished in the schedule as to the amount of compensation paid employes, and, further, that the premium should be subject to adjustment if the compensation was greater or less than the estimated sum stated in the schedule. The compensation paid, was in fact greater than the amount so estimated. It was held that the \$113.90, the amount estimated, was not conclusive of the amount of

the premium, and the insurer could recover the additional amount shown to be due.

Fidelity & Casualty Co. of New York v. J. W. Crowder Drug Co., Texas Civil Appeals, 166 S. W. 1186.

INTOXICATING LIQUORS—VALIDITY OF DRUGGIST'S LICENSE—TRANSPORTATION.

A civil action was brought by a regularly licensed druggist and pharmacist in North Carolina against an express company to recover a statutory penalty for non-delivery of goods. The plaintiff also held a license from the sheriff of the county as a retail liquor dealer. He ordered six quarts of cognac brandy from a firm in Tennessee and paid charges thereon, but delivery was refused by the express company. The plaintiff alleged that it was his purpose to sell the brandy for profit, but only in the way of filling prescriptions in the *bona fide* pursuit of his calling, and this was well known to the defendant's agent. It appeared that the plaintiff had not applied for his license to sell liquor to the board of aldermen of the town in which he did business, nor to the county commissioners, as required by the North Carolina statute, but had merely gone to the sheriff for his privilege license tax, and the sheriff had given him the license. The exception in the statute permitting the sale of intoxicating liquor by pharmacists on physicians' certificates, as an exception to the public policy of the state forbidding its manufacture and sale, does not, by the express terms of the provision, relieve druggists from complying with the law as to license and taxes. The plaintiff's license was therefore held to be invalid. As a sale of liquor by him would have been unlawful, it was held that the court would not aid him in this intended breach of the criminal law, nor penalize one who, knowing the facts, declined to deliver the liquor, in furtherance of his unlawful purpose.

Smith v. Southern Express Co., North Carolina Supreme Court, 82 S. E. 16.

DISTINCTION BETWEEN "SURETY" AND "GUARANTOR."

An agency contract to sell medicines and extracts within fixed territory required the agent to canvass the territory, keep a record of all goods sold, and to make reports of

sales and collections and of all goods on hand, and to pay wholesale prices, and at the termination of the agreement to pay the whole amount remaining unpaid and return the goods on hand. A separate instrument recited that the undersigned jointly and severally guaranteed the payment of a specified sum for medicines, extracts, etc., in the manner provided for in the contract. This instrument was signed by two obligors at a place indicated by the words "Sureties sign here," and an added statement read: "The above-mentioned sureties will be furnished, upon request, at any time, a statement of the amount due the company, from the party of the second part." In an action against the agent and the two signers of the instrument it was held that the instrument created only a guaranty, and the signers were not sureties.

Contracts of suretyship and of guaranty have much in common—in both the undertaking is to answer for the debt, default, or miscarriage of another. The difference is that a surety insures the debt, is bound with his principal as an original promisor, is a debtor from the beginning; a guarantor answers for the debtor's solvency, must make good the consequences of his principal's failure to pay or perform, is bound only in case his principal is unable to pay or perform. From this difference, one consequence of importance in respect of the procedure to be followed in the enforcement of liability results. A principal and a surety, being equally bound, may be joined in the same suit; but a guarantor, being bound by a separate contract, must be sued separately. Judgment for the guarantors was therefore affirmed.

J. R. Watkins Medical Co. v. Lovelady, Alabama Supreme Court, 65 So. 52.

SALE OF DRUGS REGULATED.

The Massachusetts Legislature passed an act, which goes into effect January 1, making the sale of opium, morphine and other narcotic drugs unlawful, except when there is a written prescription or order. The new law requires that the prescription must be retained on file by the druggist filling it for at least two years and shall be open at all times to inspection by the State Board of Health, the Board of Registration in Pharmacy and the police. It shall not be refilled except upon the order of the prescriber. The act

does not apply to prescriptions or remedies containing a small stated amount of the drugs. Violation of the act is punishable by a fine of from \$50 to \$1000, imprisonment for not more than one year or both.

PORT COCKBURN TRIP.

We are informed by Mr. C. C. Williams, the General Passenger Agent of the C. R. R., that the itinerary of the trip to Port Cockburn, published in the last issue of the JOURNAL, has been changed since it was furnished the JOURNAL.

It would be advisable, therefore, for members intending to take this trip to note this, and to inform themselves, by consultation with the Canadian Pacific Railway Company, No. 7, Fort Street West, Detroit, as to the time of the departure of trains and connections therewith.

Council Business

COUNCIL LETTER No. 27.

PHILADELPHIA, PA., July 1, 1914.

To the Members of the Council:

In the previous Council Letter, two motions Nos. 40 were presented, the second number (p. 68) (*Assignment of Patent Rights for Improved Package for Antiseptic Poisons*) was a typographical error and should have been No. 41. Please correct.

Motion No. 40 (C. L. No. 26, p. 67), on appropriation of \$50 or less to Section on Pharmacopœias and Formularies, has received a majority of affirmative votes.

The following communication has been received from Franklin M. Apple:—

"Replying to Council Letter No. 26, I wish to record my objection to the motion numbered 40 pertaining to the Wm. S. Merrell Chemical Company's offer to the Association.

"The offer made by the Wm. S. Merrell Chemical Company is *not* identical with the one previously made by The Norwich Pharmacal Company, as a careful reading of the two offers will reveal.

"In Council Letter No. 12, p. 29, will be found the following conditions pertaining to the offer of The Norwich Pharmacal Company: 'This we propose ——— Serial No. 801,748 and we hereby agree to bear all expense incident to the prosecution and securing of said patent,' and on page 31 of the same letter will be found a copy of a letter from their attorneys in Washington, D. C.,

which verifies their (The Norwich Pharmacal Company's) offer to deliver a valid patent to the Association without any cost whatsoever to the Association.

"The offer of the Wm. S. Merrell Chemical Company is *not* accompanied by any such provision to tender to the Association a valid patent; but it offers merely whatsoever rights they may have in the case, which up to this date have not been determined by anyone to my knowledge. Under such conditions, the Association would be compelled to engage an attorney and ask the assistance of the Wm. S. Merrell Chemical Company to prove that the claims set forth in the application are based upon facts that leave no doubt as to the value of the invention.

"One party agrees to deliver a finished product, but the other party offers to deliver a product only partially completed—to what extent cannot be accurately determined by the evidence offered.

"As I see the facts, President Beringer has correctly voiced the further objections to the offer of the Wm. S. Merrell Chemical Company in Council Letter No. 24, p. 63 and 64.

"Concerning the suggestions made by Harry B. Mason in Council Letter No. 20, I wish to state that I endorse the following ones without reserve: Nos. 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 13 and 14. I would modify No. 5 so that a brief synopsis of the committee reports be presented to the Council for its consideration and if deemed wise by it, referred to the Association for discussion. Before adopting No. 12, provision must be made to protect the material offered for the benefit of the Journal of the A. Ph. A. No. 13 is a very radical move and should be given very serious attention before its adoption. This proposed move indicates the necessity of using very great care in selecting presiding officers for the several sections. It might be well to have an Advisory Board, chosen by the Council, to censor the nominees for presiding officers of the several sections in the general interest of the Association. I most heartily endorse the idea of abolishing the Section on Pharmacopœias and Formularies, as its work comes under the scope of the Committee on Practical Pharmacy and Dispensing mostly, hence you very materially weaken this Section, which is most unfortunate indeed. The only advantage gained by its existence is the fact that a member *not* actively engaged in the retail drug business is eligible to hold office, whereas it is obligatory that he be so engaged to preside over the destinies of the Section on Practical Pharmacy and Dispensing.

"Until it is proven that another Section can properly look after the questions that now are the property of the Committee on Commercial Interests, I am opposed to the discontinuing of the oldest section of the Association. It was established in 1887, when

the Association was only twenty-five years old, and has continued to prove to be a vital part of the Association's activities. It is needed more today than at any previous day, and all that is needed is proper supervision and direction. The bread and butter line is too prominent a part in the life of the majority of our members to be treated lightly. What is demanded today is the possibility of *practically applying* one's knowledge to gain an honorable living, and provide for the proverbial rainy day."

The following letter has been received from President G. M. Beringer:—

"From the letter of Prof. Koch (Letter No. 26, pages 67-68), I fear that he has mistaken my position. His communication in no wise answers the arguments advanced by me in Council Letter No. 24. I am not averse to the acceptance of any proposition of this character for the protection of the public by additional safeguards in the handling of poisons. To the contrary, I am ready to vote in favor of the acceptance of these propositions, provided they are not coupled with conditions that would be unwise for the Association to accept.

"If the members will kindly peruse the letter of the Norwich Pharmacal Company (Letter No. 12, page 30) and the letter of the William S. Merrell Chemical Company (Letter No. 21, page 53), they should not fail to understand my point. The first is a generous offer to transfer all right and title to the American Pharmaceutical Association without any expense to the Association, with no condition attached except the right on the part of the assignee to continue manufacturing these tablets. The latter proposition contained two conditions, which as pointed out in my previous communication, may prove burdensome and objectionable.

"The form of the assignment is not what I have directed attention to, but the letter accompanying such assignment which, doubtless, is intended by the William S. Merrell Chemical Company as a part of their offer and contract and should be so considered by the Council. The wording of the motion submitted by Drs. Beal and Koch in the first resolution refers to their communication and undoubtedly covers the conditions named therein.

"In order to get the matter squarely before the Council, I will move that paragraph *one* of the motion be amended to read:

"Resolved, That the American Pharmaceutical Association accept the completed assignment of the patent rights of the William S. Merrell Chemical Company in and to a design patent for a new, original and useful improvement in packages for Antiseptic Poisons, serial number 817,364, provided such patent and assignment is completed without expense to the Association or associated with any other conditions than that named in the assignment."

Do you approve above motion, which will include approval of the original motion as

amended and as a whole, and will be regarded as *Motion No. 42 (Amended Motion for Assignment of Patent Rights or Improved Package for Antiseptic Poisons)*.

The following communication has been received from Hugh Craig:—

"I am particularly impressed with Mr. Wilbert's communication and I believe that for the most part his suggestions are good ones, because there is a real and growing necessity for some change in the procedure of the Association, to obviate a great deal of wasting of time and to coordinate the interests of the various sections. While Mr. Wilbert suggests a great many simultaneous sessions, I believe that this matter could be adjusted each year quite satisfactorily. It might be a little out of place for me to comment particularly upon his suggestion for the elimination of the Section on Commercial Interests because of my connection with an organization which really covers the ground that this section is designed to cover. Pharmacally considered, the commercial side of the calling of the druggists should have the limitations that Mr. Wilbert specifies and within the limitations it could quite well be handled in the Section on Practical Pharmacy.

"I particularly favor, however, his suggestion to eliminate the Section on Pharmacopœias and Formularies. This has always seemed to me an unnecessary subdivision. Considered from the standpoint of legal standards, the Pharmacopœia and the National Formulary would come within the purview of the Section on Education and Legislation and they really have no other place. From the standpoint of pharmaceutical practice embracing processes and formulas, all books having to do with the preparation of drugs would come most naturally within the purview of the Section on Practical Pharmacy and nowhere else. Of course, I recognize that this might have a tendency to crowd unduly the program of the two sections to which the work would be allotted, but I believe that this crowding can be guarded against, if the chairmen of the sections will but refrain from perhaps a commendable desire to have a great many papers rather than a few papers on timely topics and permit an opportunity for discussion on the floor.

"The matter of the standing of the so-called Women's Section, was one upon which my position is quite well known from the effort I made to have at least the name of this subdivision changed at the Nashville convention. Mr. Wilbert states what are uncontrovertible facts with reference to the constitutional standing of such a division of the Association and heartened by his suggestion I desire at this time to offer the following motion:

"*Resolved*, That the name of the subdivision of the American Pharmaceutical Association now known as the Women's Sec-

tion be changed to the Women's Auxiliary, and that all matters of constitution and by-laws of this Auxiliary be left to the determination of those who shall constitute it, with the provision that membership in the Auxiliary be limited to the women members of the Association and to the women members of the immediate family of all members of the Association."

"I do not agree with Mr. Wilbert with reference to the abolition of the House of Delegates, as I believe this body performs a very necessary service as a clearing house under present conditions. I think, however, that it would be much better, if provision was made for having the Council meet as a committee on resolutions—to use a popular term—and perform the work now carried out by the House of Delegates. In order that delegates might secure proper recognition my suggestion would embody a plan for having them certified to the Council and allowing them full voice on the floor of the meeting, which I have suggested, this meeting not to have any voting, the disposition of the various matters being left to the Council.

"In another matter I do not agree with Mr. Wilbert, and that is, in his suggestion that alternates be recognized by the Council to represent absent members. The business of the Council is continuous throughout the year and for this reason an alternate could not be expected to be in touch with the status of various matters that perhaps had previously come before the Council. It is, however, greatly to be desired that there be at each annual convention the fullest possible attendance of the members of the Council and this desirability should be urged upon each member of the body on every possible occasion."

Do you approve of motion as above offered? It will be known as *Motion No. 43 (In Women's Section, A. Ph. A.)*

The following communication has been received from Frederick J. Wulling:—

"Council Letter No. 26 at hand. Mr. Wilbert's letter includes some of my oft-times expressed sentiments. I believe the multiplication of sections was unwise. The sections on commercial interests, history, pharmacopœias and formularies could be made standing committees of other sections or of the Association, with definite periods of time and places on the program for their reports. The sessions of the three sections ought to be held concurrently to save time. A very much greater number of members read the proceedings than attend the sessions. Indeed, I venture to say most members get more out of reading the proceedings than out of listening to them.

"In the general and section sessions, especially in the latter, too much time is wasted because not enough time and care is devoted to the preparation of the programs. The reading and discussion of papers should be

based on a time schedule, carefully prepared beforehand by the chairmen, who, in the absence of the fullest cooperation on part of the participants in the program, should arbitrarily set limits to papers and their discussions and then adhere as strictly to the time schedule as a train dispatcher does to his. That kind of work and courage on part of the chairmen and cooperation on part of participants would unquestionably be appreciated by practically everyone. We have tested this out here in Minnesota, where for the past ten years the Scientific Section of the State Association has been conducted on a time schedule with never a minute's deviation and to everybody's satisfaction and profit. Under this system every participant is held to the point and gabfests are simply impossible, all with the result that an astonishingly large amount of really meaty transactions can be conducted in a session of average length. The sessions, especially of the sections, should not constitute the evolution of a program, but *the presentation of an already evolved program*. The elimination of non-essentials would save an amount of time that would astonish many.

"With this kind of management the Association would need not more than three days and the other two Associations one day each. If these three bodies should hold their meetings quasi-concurrently, as I think they should, the A. Ph. A. could meet on Mondays, Wednesdays and Fridays and the other two bodies on Tuesdays and Thursdays with one session each, each day.

"Mr. Wilbert's suggestion of alternates for members of the Council who are unable to attend the meeting should receive consideration. The members unable to attend should have the designation of the alternates. Possibly it should be the duty as well as the power of each Council member to so designate.

"As I see the matter, there is no warrant for a Women's Section. There would be no objection to a non-official Women's Auxiliary.

"I believe, too, that we ought to hold our meetings in the winter time or other than the summer time and that the meetings ought to be devoted more seriously and exclusively to the business of the Association. Now we hold our meetings during the holiday period of the year and transact our business with the holiday spirit and mood on us. Those who care to combine a holiday with the meetings could do so as well in winter. The time ought to be past when pharmacists must be induced to attend meetings by the promise of a good time."

The following communication has been received from Albert Schneider:—

In reference to Mr. Mason's letter of May 16th I would urge most careful consideration. Let us make haste slowly in this matter. The A. Ph. A. has done most excellent work in the past and it has a most excellent reputation. I agree with Mr. Mason that

certain changes in the manner of conducting the annual meetings of the Association are very necessary, but I for one would not think it wise to cut out any of the sections. I believe the objectionable features referred to by Mr. Mason can be corrected by certain rearrangements of the section work. To this end I hereby submit the following. Establish four sections, each section with four, or more, divisions, as follows:

I. COMMERCIAL SECTION—

1. Division of Foreign and Domestic Drug Market
2. Division of Advertising
3. Division of Manufacture
4. Division of Retail Drug Trade

II. LABORATORY SECTION—

1. Division of Chemistry
2. Division of Botany and Pharmacognosy
3. Division of Materia Medica and Pharmacology
4. Division of Bacteriology and Sanitation

III. SECTION ON PHARMACY AND DISPENSING—

1. Division of U. S. P. and N. F.
2. Division of Dispensing
3. Division of Retail Manufacture
4. Division of Historical Pharmacy

IV. SECTION ON EDUCATION AND LEGISLATION—

1. Division of Colleges of Pharmacy
2. Division of State Legislation
3. Division of National Legislation
4. Division of Boards of Pharmacy

I have purposely mixed the different interests as represented by the main divisions or sections, so as not to be accused of showing partiality. The four sections cover drug trade, investigation and research, pharmaceutical methods and education, in fact the entire field of legitimate pharmaceutical interest. Each section should have full control of the subdivisions. It is my idea that there should not be separate meetings for the section divisions, but that such divisions as may be represented by readers of papers, are to meet with the rest of the divisions of such section, at one and the same session.

The above are suggestions which are quite self-explanatory. I believe if they were adopted they would overcome the confusion referred to by Mr. Mason without abandoning any of the sections now in existence. Under the proposed plan, the Conference of Faculties and the Association of Boards could be made Divisions of Section II; or they could continue as before provided that none of their meetings interfere with the work of the A. Ph. A."

Motion No. 44 (Applications for Membership). You are requested to vote on the following applications for membership:—

No. 197. Walter Hines Whisenant, 117 E.

Houston St., San Antonio, Texas, rec. by Herman A. Nester and E. G. Eberle.

No. 198. Robert T. Chambers, 529 San Pedro Ave., San Antonio, Texas, rec. by Herman A. Nester and E. G. Eberle.

No. 199. John W. Callens, 201 De Leard St., Monroe, La., rec. by Philip Asher and J. H. Beal.

No. 200. Emile Joseph Burvant, 2308 Lacharpe St., New Orleans, La., rec. by Philip Asher and J. H. Beal.

No. 201. Charles Friedgen, 1220 Amsterdam Ave., New York, N. Y., rec. by Louis Berger and Leon Lascoff.

No. 202. James H. Jones, 350 E. Fordham Road, New York, N. Y., rec. by Louis Berger and J. Leon Lascoff.

No. 203. George Waterman Smith, Honolulu, Territory Hawaii, rec. by Frank L. Gibson and J. H. Beal.

No. 204. Louis Frank Thumser, 232 Monticello Ave., Jersey City, N. J., rec. by Wm. C. Anderson and Jacob Reffuss.

No. 205. Ernest Reif, 1251 North Second St., Philadelphia, Pa., rec. by A. J. Staudt and Franklin M. Apple.

No. 206. Frank Randall Rohrman, 4603 Wayne Ave., Philadelphia, Pa., rec. by Franklin M. Apple and George M. Beringer.

No. 207. Virgil Earl Pirtle, Bonne Terre, Mo., rec. by H. M. Whelpley and J. W. Mackelden.

No. 208. Junius Blanton Linn, Canton, Mo., rec. by H. M. Whelpley and Francis Hemm.

No. 209. D. W. Casey, Red Oak, Iowa, rec. by E. O. Kagy and R. L. Parker.

J. W. ENGLAND,
Secretary of the Council.

414 N. 33d St.

<>

COUNCIL LETTER No. 28.

PHILADELPHIA, PA., July 14, 1914.

To the Members of the Council:

J. W. England, Chairman of Committee on Publication, reports as follows:—

"It will be recalled by the members of the Council that Motion No. 30 (C. L. No. 17) provided that the resignation of Dr. James H. Beal as Editor and General Secretary be accepted to take effect September 1, 1914, and Motion No. 31, that Dr. Beal be relieved of the active work of the General Secretaryship and Editorship of the JOURNAL as far as possible, and that he be authorized to make the best arrangements he could with Mr. Ernest C. Marshall or other person or persons that he might select, to carry on the work of the offices of the General Secretary and Editor under his direction until September 1st.

Dr. Beal writes that Mr. Ernest C. Marshall has agreed to serve as Acting Editor and Acting General Secretary, beginning June 1, 1914, at the rate of \$3000 per year from the date of his assumption of duties, and that the allowance is to be in full for all of his services, and that he is not to receive additional compensation for work done as Advertising Manager."

The following communication has been received from President George M. Beringer:—

"I have been greatly pleased to note the interest that is being taken by our members in the discussion regarding the method of procedure at the annual meetings of the Association. From the multitude of counselors, no doubt, we will be able to draw some conclusions that will materially aid the situation. The President is giving these several suggestions very careful consideration and at the proper time may offer some recommendations concerning these.

From the discussion regarding the matter of our lady friends of the Women's Section, one might imagine that the members of the Council were all confirmed bachelors. We must remember that we are living in the twentieth century when women have ideas of their own and we must, at least, consult them before taking any definite action on the questions involved.

I believe that the members of the Council will agree with me that it is not desirable to take hasty action on the motion offered by Mr. Craig, and I am likewise constrained to question whether a motion of this character, in a parliamentary sense, is in order. The status of all of our Sections and standing committees of the Association is fixed in the by-laws and not simply by a motion or resolution offered in the interim between meetings and voted upon by mail.

Further, I believe that at the forthcoming meeting, action will be taken by the Association towards fixing the status of our good lady friends, to whom we owe so much, both as to the proper title for their section or branch or auxiliary, whatever we may decide to name it, and likewise their standing as members of the Association.

Pending such proper action of the Association or its Council at Detroit, I will move that the consideration of Mr. Craig's motion, known as Motion No. 43, be postponed until the meeting of the Association in Detroit."

Do you approve of substitute motion as above presented? It will be known as *Motion 45 (Postponement of Action on Motion No. 43)*.

Lucius E. Sayre writes as follows:—

"While I approve of the plan of condensation of sections, I do not like to see the Section on Pharmacopœias and Formularies discontinued. I know the desire of those who proposed this section and am in sympathy with their motives and purposes. Let them have a fair chance of a few years to see what they can do. They represent a young

and enthusiastic element in our Association who believe in certain reforms and progress along the line of this particular work. Please read my article on the subject of this section in a paper presented at Denver. I should not object to merging the Section on Practical Pharmacy and Dispensing with this section and give it a new title, e. g., Section on Pharmacopœias, Formularies and Dispensing. This title will embrace practical pharmacy, to my notion."

C. Lewis Diehl writes as follows:—

"If the motion on the 'Assignment of Patent Rights for Improved Package for Antiseptic Poisons' had been presented under the proper number, that is No. 41 instead of the duplicate number 40, I should have voted 'No,' and given my reasons for doing so—these reasons being in part on the grounds presented by Mr. Beringer, and more recently by Mr. Apple. But another reason, which is but lightly touched upon by Mr. Beringer, is, this, that while the offer of the Norwich Pharmacal Co. deals with an article which has been prominently discussed for admission into the U. S. P., the article covered by the offer of the Wm. S. Merrell Chemical Co.—aside from the fact that it is offered conditionally—is not generally known; has so far as I know, not been discussed, and certainly has not been proposed for admission into the U. S. P.

Indeed, if it had been the purpose to advertise this product, which is up to the present time exclusively controlled by its originators, the latter could have resorted to no better method than to relinquish their rights, with or without conditions, to the American Pharmaceutical Association; for, whether discussed for admission into the U. S. P., or not, the demand for this article, if any, is most likely hereafter to be for the product of the originators.

I do not approve the promiscuous ownership of patent-rights by the Association, and certainly not in any case in which it is not clearly evident that it is the only (or best) way to safe-guard the public. I am, therefore, constrained to vote in the negative on Mr. Beringer's resolution, covered by Motion No. 42."

C. Lewis Diehl, Chairman of the Committee on National Formulary, discusses the work of the revision of the N. F. IV, as follows:

"Inasmuch as it has been announced that the work of the revision of the U. S. P. IX has so far advanced that the printer can begin to set up the text in type on or about the first of this month (July), it has now become imperatively necessary to round up the revision of the N. F. IV so that it will be practically ready to go to press shortly after the Detroit meeting.

We have, since the date of the Nashville meeting, accomplished much towards this end; have revised and corrected the mimeograph copies of the text then presented, as

well as of the small number of unfinished monographs, including the chapter on sterilization; have prepared and mimeographed the text for some sixty or more articles carried over from the U. S. P. VIII, reviewed and supplemented the dosage with the assistance of Dr. Cohen, and have made substantial progress on the definition of ingredients that are required for the preparations and are not (or no longer) defined in the Pharmacopœia.

But there are some questions still in controversy, which cannot be settled except by tedious correspondence and consequent delay. It is, therefore, very desirable to arrange for a meeting of all the members of the Committee for several days' conference, so that these questions can be definitely settled and the last word said on the mimeograph proofs. Unless this is done, the responsibility on a number of important points will have to rest with the few members composing Sub-Committee "D," who are working directly with the preparation of the manuscript, and this responsibility the members of the Sub-Committee (acting as an 'Executive Committee') very properly decline to assume.

The necessity for this conference is emphatically voiced by Mr. Cook, who, as acting Chairman of Sub-Committee "D," has been indefatigable in this important service, and who, aside of being handicapped by other important duties, has very generously assumed the duties of cognately assembling the details of progress in our work, so that the Bulletin might be issued with fair regularity during a prolonged period of illness—almost continuous since October of last year—which had incapacitated me for the strenuous work involved in conducting the revision during much of that time.

For the reasons thus explained, I therefore respectfully ask your authority to issue a call for a meeting of the Committee on National Formulary for the purpose of a personal Conference during the two days succeeding the last session of the Association, at Detroit, with the usual allowance for expenses incurred by them for transportation, sleeper, meals *en-route*, and (not exceeding) two days at hotel.

Owing to the proximity of the location of many of the members to Detroit, the expense of this conference, if authorized, will be well within the appropriations for this purpose on previous occasions.

The proposed date, following the close of the last session, is suggested because some of the members—Mr. Beringer, Mr. Cook and others—will be too busy at an earlier date, and probably unable to attend, if the Conference is held before the opening session of the Association."

The Secretary of the Council wrote to Professor Diehl, as follows:—

"In re. your letter of the 6th inst., addressed to the Council, it seems to me that it would be better to appropriate a definite sum with which to pay the expenses, etc., of the

fifteen members of the Committee on National Formulary for two days, and I would suggest that a motion be offered stating the maximum amount desired. All expenditures in excess of twenty-five dollars must be approved by the Finance Committee before they can be acted upon by the Council. If you will state the necessary amount, I will submit the motion to the Finance Committee, and then to the Council. But since this expenditure is to be made *after* the Council is to meet at Detroit, why not leave the matter of appropriation rest until then? In the meanwhile, the authorization of the meeting of the Committee on National Formulary can be placed before the Council."

The following reply was received from Professor Diehl:—

"My object was for authority to call a meeting of all the members of the N. F. Committee, of course at the expense of the Association. The matter of appropriation, as suggested by you, had better rest until the Council meets at Detroit. Incidentally, we will then know approximately how much will be required."

Do you authorize the issuance of a call for a meeting of the Committee on National Formulary for the purpose of a personal conference during the two days succeeding the last session of the Association at Detroit, the matter of appropriation for expenses incurred by the committeemen for transportation, sleeper, hotel expenses, etc., to be passed upon by the Council at the Detroit meeting? This will be known as *Motion No. 46 (Authorization of Special Meeting of Committee on National Formulary after Sixty-second Annual Convention of A. Ph. A.)*

J. W. ENGLAND,

Secretary of the Council.

415 N. 33d Street.

COUNCIL LETTER No. 29.

Philadelphia, Ja., July 29, 1914.

To the Members of the Council:

Motions No. 39 (Organization of Columbus Branch, A. Ph. A.), No. 44 (Election of Members; applications Nos. 197 to 281 inclusive), No. 45 (Postponement of action on Motion No. 43), and No. 46 (Authorization of Special Meeting of Committee on National Formulary after sixty-second Annual Convention of the A. Ph. A.), have each received a majority of affirmative votes.

George B. Kauffman, of Columbus, O., has been elected as representative to the Council by the Columbus Branch. The members of the Council now number forty.

The following communication has been received from Julius A. Koch:

"In order to answer the various objections to the acceptance of the patent right on 'Antiseptic Leaflets,' I requested The William S. Merrell Chemical Company to make their offer more specific and am enclosing their reply which kindly insert in the next Council letter. I note Prof. Diehl's remarks on the subject and wish to reply only in so far as it seems to me necessary in justification of The William S. Merrell Chemical Company. Some months ago the 'Leaflets' came to my notice and to my mind seemed to meet our needs so well that I brought them to the attention of many of my friends, both physicians and pharmacists. The favor with which the idea was received, led me to bring it to notice of the Chairman of the Revision Committee and to request The William S. Merrell Chemical Company to assign their rights to the A. Ph. A., with which request they promptly complied. I am solely responsible for bringing 'Antiseptic Leaflets' before the Council and wish to state that I have no interests in the same except as a matter of public good. I still believe this form of dispensing corrosive sublimate for making antiseptic solution to be the safest for the prevention of accident and suicide and should like to see it adapted in the U. S. Pharmacopœia. For this reason I asked The Merrell Chemical Co. to assign to the Association the patent rights."

Attached to Prof. Koch's letter is the following communication:

"THE WM. S. MERRELL CHEMICAL CO.
Home Offices and Laboratories, Cincinnati.

July 15, 1914.

Mr. J. A. Koch, Strattonville, Pa.:

Dear Sir:—Replying to your letter of the 11th instant, our intention is to turn over our right to the patent which is now being prosecuted before the commissioner and which we intend to complete and secure issuance of the patent in our name, if a patent is granted, as we believe it will be.

Our assignment was intended to turn over to the American Pharmaceutical Association our rights as stated in a previous communication. We do not of course, guarantee that we shall secure the patent but of course if we fail to do so, the product becomes public property which as we understand it, would answer your purpose nearly if not quite as well.

In specific reply let us state that it is our intention to prosecute our claims to completion. In fact, our patent attorney has not even been advised of our assignment and is continuing prosecution as if nothing of the kind had occurred.

Very truly yours,

THE WM. S. MERRELL CHEMICAL COMPANY,
CHAS. G. MERRELL."

J. W. ENGLAND,
Secretary of the Council.

415 North Thirty-third St.

Changes of Address

All changes of address of members should be sent to the General Secretary promptly.

The Association will not be responsible for non-delivery of the Annual Volume or Year Book, or of the JOURNAL unless notice of change of address is received before shipment or mailing.

Both the old and the new address should be given, thus:

HENRY MILTON,
From 2342 Albion Place, St. Louis, Mo.
To 278 Dartmouth St., Boston, Mass.

Titles or degrees to be used in publications or in the official records should be given, and names should be *plainly* written, or type-written.

UNITED STATES PUBLIC HEALTH SERVICE.

List of Changes of Stations and Duties of Commissioned and Other Officers of the United States Public Health Service, for the seven days ended June 24, 1914:—

Assistant Surgeon-General L. E. Cofer. Directed to proceed to Philadelphia, Pa., Reedy Island, and Delaware Breakwater Quarantines for the purpose of making an inspection of the operations of the quarantine service upon the Delaware River. June 16, 1914.

Assistant Surgeon-General J. W. Trask. Granted 1 day's leave of absence June 19, 1914. June 17, 1914.

Senior Surgeon H. W. Austin. Granted 10 days' leave of absence from June 25, 1914. June 24, 1914.

Surgeon George M. Magruder. Re-assigned for duty at Portland, Oregon, effective Feb. 23, 1914. June 16, 1914.

Surgeon R. M. Woodward. Detailed to attend the conference of the Pacific Coast Federation of Sex Hygiene at San Francisco, Cal., July 1, 1914. June 22, 1914.

Surgeon G. M. Guiteras. Granted 2 days' leave of absence, June 21-22, 1914. June 19, 1914.

Surgeon L. L. Lumsden. Directed to visit Baltimore and such other points in the State of Maryland as may be found necessary on business connected with the investigation of rural sanitation. June 10, 1914.

Surgeon J. F. Anderson. Detailed to attend a conference called by the licensed manufacturers of biologic products to be held at Atlantic City, N. J., June 22, 1914, for consideration of legal methods and procedures in the control of biologic products. June 16, 1914.

Surgeon Dunlop Moore. Granted 1 month's leave of absence from July 21, 1914. June 22, 1914.

Surgeon J. Goldberger. Directed to proceed, at such times as may be necessary, to Savannah, Ga., Spartanburg, S. C., and other points in the Southern States to organize and supervise the pellagra studies. June 16, 1914.

Surgeon M. K. Gwyn. Granted 30 days' leave of absence, on account of sickness, from June 14, 1914. June 16, 1914.

Passed Assistant Surgeon E. A. Sweet. Relieved from duty at the Gulf Quarantine Station and directed to proceed to the Mo-

bile Quarantine Station and assume temporary charge. June 19, 1914.

Assistant Surgeon G. A. Kempf. Granted 21 days' leave of absence from June 29, 1914. June 19, 1914.

Assistant Surgeon J. B. Laughlin. Relieved from duty in charge of the Mobile Quarantine Station, and directed to proceed to New Albany, Miss., and report to Surgeon L. L. Lumsden for duty in field investigations. June 19, 1914.

Professor E. B. Phelps. Directed to proceed to Cincinnati, Ohio, and such other places on the Ohio River watershed as may be necessary, for conference in regard to the investigations of the pollution of the Ohio River now being carried on. June 16, 1914.

Acting Assistant Surgeon L. E. Werry. Granted 4 days' leave of absence from June 4 1914. June 3, 1914.

Pharmacist E. M. Holt. Directed upon completion of temporary duty at the New Orleans Quarantine Station to return to station at the Marine Hospital, Savannah, Ga. June 23, 1914.

List of Changes of Duties and Stations of Commissioned and Other Officers of the United States Public Health Service, for the seven days ended July 23, 1914.
